CHAPTER ONE

INTRODUCTION

GENERAL

One of the most hurricane vulnerable areas of the United States is the southeastern region of Florida. This region includes the Treasure Coast, which is comprised of Indian River, St. Lucie, Martin, and Palm Beach Counties. Historically there has been a high frequency of hurricanes which have affected this region of Florida, either directly or indirectly. The tracks of the primary storms affecting the region are shown in the documentation of the Hazards Analysis - Appendix B.

PURPOSE

The purpose of this Study is to provide emergency management officials with realistic data, quantifying the major factors involved in hurricane evacuation decision-making. The technical data presented in this report are not intended to replace the detailed operations plans developed by each of the counties and municipalities within the Study area. Rather, these data will provide a framework within which each county can update and revise their hurricane evacuation plan and from which operational procedures and guides can be developed for future hurricane threats.

The Treasure Coast Region Hurricane Evacuation Study is a partial update of Lower Southeast Florida Hurricane Evacuation Study. Palm Beach County was included in the previous study. See Figure 1-1 (page 1-4) for the map of the study area. This study utilizes the information from the SLOSH (Sea, Lake, and Overland Surges from Hurricanes) models for the Cape Canaveral Basin (Indian River County) and the Palm Beach Basin (St. Lucie, Martin, and Palm Beach Counties), which were developed by the National Hurricane Center (NHC), National Oceanic and Atmospheric Administration (NOAA). The tremendous development and population growth of the region, necessitated the current work. The

primary emphasis of this study was the identification of life-threatening flooding resulting from hurricanes and the safe evacuation of populations from unsafe areas and conditions within the region.

FUNDING

The Treasure Coast Region Hurricane Evacuation Study was funded by the Federal Emergency Management Agency, the U. S. Army Corps of Engineers, and the State of Florida Department of Community Affairs, Division of Emergency Management. Local officials and agencies provided their input without direct charge to the study funds.

AUTHORITY

The study authority for the Corps of Engineers is Section 206 of the Flood Control Act of 1960 (Public Law 86-645), and study authority for the Federal Emergency Management Agency is the Disaster Relief Act of 1974 (Public Law 93-288). These laws authorize the allocation of resources for planning activities related to hurricane preparedness. Authority for State of Florida involvement in the study is established by State Emergency Management Act, Chapter 252 (Sections 252.31 through 252.60), Florida Statutes (F.S.).

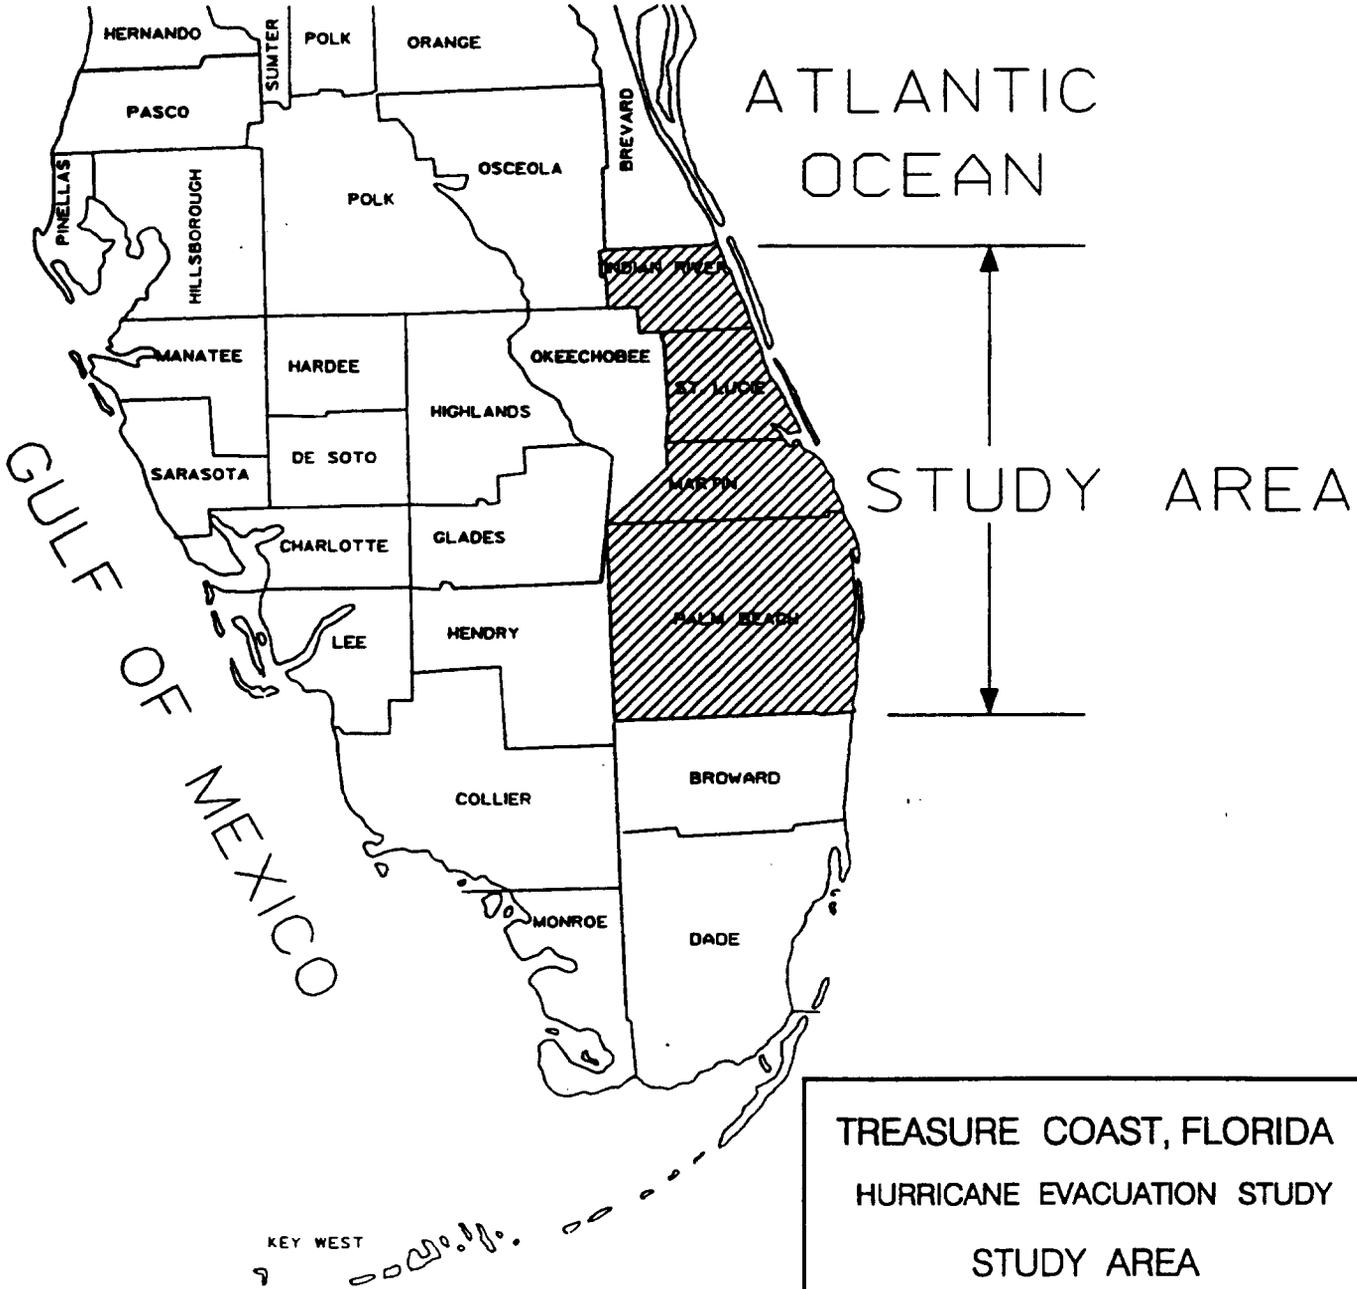

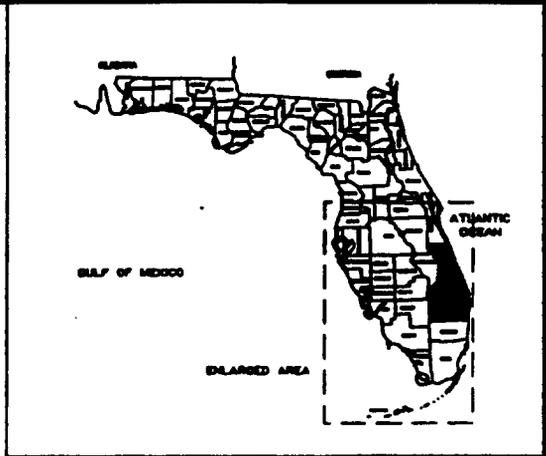

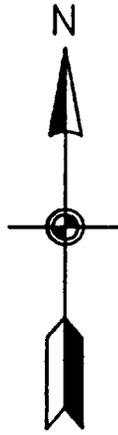

This study was conducted by the Jacksonville District, U.S. Army Corps of Engineers, which provided the project management and technical assistance in accordance with the Corps of Engineers' publication, Technical Guidelines for Hurricane Evacuation Studies, November 1984, and the Federal Emergency Management Agency's publication, CPG-16, A Guide to Hurricane Preparedness Planning for State and Local Officials, December 1984.

DESCRIPTION OF STUDY AREA

A. Geography.

There are four (4) counties in the study area: Indian River, St. Lucie, Martin, and Palm Beach. The entire study area includes over 100-miles of coastline with islands and barrier

islands, some of which are heavily populated. This includes the areas of Orchid City; Indian River Shores; Vero Beach in Indian River County; Hutchinson Island in St. Lucie and Martin Counties; and Jensen Beach, Hobe Sound, and Jupiter Island, also in Martin County. The study area includes West Palm Beach, Lake Worth, Boynton Beach, Delray Beach, and Boca Raton in Palm Beach County. A Category 5 Hurricane has the potential to flood all of these areas. The study area is shown in Figure 1-1.

TREASURE COAST, FLORIDA
HURRICANE EVACUATION STUDY
STUDY AREA

FIGURE 1-1

B. Topography.

South central Florida is particularly exposed to the dangers presented by hurricanes due to its topography. The region is largely a flat, low-lying plain. A low coastal ridge 3 to 10 miles wide separates the St. Johns River area from the coastal area and ranges up to an elevation of 30 feet. Lake Okeechobee lies on the west boundary of Martin and Palm Beach Counties.

The coastal areas could be affected by the very high waves from a severe hurricane largely due to the relatively narrow shelf in the southern portion of the Treasure Coast Region. Waves are less severe and surge is more pronounced in the northern area of the study area.

C. Bathymetry.

The bathymetry offshore is extremely important, since the configuration and depth of the ocean bottom has an effect on surge and wave heights. The storm surge in deeper water can be dispersed down and away from the hurricane. However, when that surge reaches a shallow, sloping bottom, it can no longer be dispersed away from the storm and consequently "piles up" as it is driven ashore by the winds. Shallow water close to shore tends to increase the magnitude of the hurricane storm surge. Areas that have a long, gently sloping offshore shelf, and relatively shallow water depths, can expect a higher surge, but smaller waves. Areas with a relatively narrow shelf, deeper water just offshore, can expect a lower storm surge, but higher waves.

The Treasure Coast Region has a relatively narrow offshore shelf with water depths that increase rapidly near shore. The shelf is quite narrow along Palm Beach County and gradually becomes wider off shore at Indian River County. General depths of 20 feet can be found about 1000 feet off shore at Palm Beach County, while the 20-foot depth contour is one-half mile off shore at Indian River County. Depths of 100 feet can be found about one (1) mile off shore at Palm Beach, while that depth is about 18 miles off shore at Vero Beach.

D. Population.

The data base for each county was developed using 1990 census and traffic analysis zonal data provided through the Florida Department of Transportation District 4 office. This source of data provided a base for permanent population parameters on a sub-county basis. Since data are regularly updated for traffic analysis zones and census units, their use provides a means to facilitate updating of the evacuation study in the future.

Seasonal and permanent dwelling unit data included the following resources:

- U.S. Census Bureau - 1990 Population and Housing Units
- Various Chamber of Commerce and travel bureaus
- Florida Department of Transportation, District 4 - 1990 Traffic Analysis Zonal data

Any future update of the study should take a careful look at the seasonal dwelling unit data in the affected areas of each county. Numbers for seasonal units were generally a combination of hotel/motel units and other units listed as seasonal in nature by the U.S. Census.

Current permanent population estimates range from approximately 93,000 in Indian River County to 900,000 in Palm Beach County. Throughout the region a significant mobile home population living outside the potential hurricane surge areas adds dramatically to the number of hurricane vulnerable people in the area. The Transportation Model Support Document lists the number of permanent dwelling units, mobile homes, and seasonal units by county by evacuation zone and TAZ (or census unit).

HISTORICAL HURRICANE ACTIVITY

A. General.

Hurricanes are a classification of tropical cyclones which are defined by the National Weather Service as nonfrontal, low pressure synoptic scale (large scale) systems that develop over tropical or subtropical waters and have a definite organized circulation. Tropical

cyclones are categorized based on the speed of the sustained (1-minute average) surface wind near the center of the storm. These categories are: Tropical Depression (winds \leq 33 knots), Tropical Storm (winds 34 to 63 knots inclusive) and Hurricanes (winds \geq 64 knots).

The geographical areas affected by tropical cyclones are referred to as tropical cyclone basins. The Atlantic tropical cyclone basin is one of six in the world and includes much of the North Atlantic Ocean, the Caribbean Sea, and the Gulf of Mexico. The official Atlantic hurricane season begins on June 1 and extends through November 30 of each year; however, occasional tropical cyclones occur outside of this period. Early season tropical cyclones are almost exclusively confined to the western Caribbean and the Gulf of Mexico. However, by the end of June or early July, the area of formation gradually shifts eastward, with a slight decline in the overall frequency of storms. By late July the frequency gradually increases, and the area of formation shifts still further eastward. By late August, tropical cyclones form over a broad area which extends eastward to near the Cape Verde Islands off the coast of Africa. The period from about August 20 through about September 15 encompasses the maximum of the Cape Verde type storms, many of which travel across the entire Atlantic Ocean. After mid-September, the frequency begins to decline and the formative area retreats westward. By early October, the area is generally confined to the western Caribbean. In November, the frequency of tropical cyclone occurrence further declines.

B. Atlantic Tropical Cyclone Basin.

Through the research efforts of the National Climate Center, in cooperation with the National Hurricane Center, records of tropical cyclone occurrences within the Atlantic tropical cyclone basin have been compiled dating back to 1871. Although other researchers have compiled fragmentary data concerning tropical cyclones within the Atlantic tropical cyclone basin back to the late fifteenth century, the years from 1871 to the present represent the complete period of the development of meteorology and organized weather services in the United States. For the 121 year period 1871 through 1991 a total of nearly 1000 tropical cyclones have occurred within the Atlantic tropical cyclone basin; however, for the years 1871 through 1885 the existing data do not allow accurate determinations of the intensities of the tropical cyclones, since available data are too fragmented and uncertain. The National Hurricane Center maintains detailed computer files of the Atlantic tropical cyclone tracks back to 1886. Of the 852 known Atlantic tropical cyclones of at least tropical storm intensity occurring during the period 1886 through 1986, 499 reached hurricane intensity.

C. Florida.

Florida is one of the more hurricane vulnerable locations along the coastline of the United States. Since 1886, 51 storms of hurricane intensity have passed within 125 miles of the Treasure Coast Region. This is an average of one hurricane every two (2) years. Before 1885 insufficient data exist to accurately determine which storms reached hurricane intensity. The number of hurricanes (direct hits) affecting southeastern Florida since 1899 have been: 4 Category 1 storms; 10 Category 2 storms; 7 Category 3 storms; 5 Category 4 storms; and no Category 5 storms.

MAJOR ANALYSES

The Treasure Coast Region Hurricane Evacuation Study consists of several related analyses that develop technical data concerning hurricane hazards, vulnerability of the population, public response to evacuation advisories, timing of evacuations, and sheltering needs for various hurricane threat situations. The major analyses comprising the Study and a description of the methodologies for each are discussed in the following paragraphs.

A. Hazards Analysis.

The hazards analysis determines the threat presented by hurricanes of various categories, tracks, and forward speeds impacting the Study Area. The Sea, Lake, and Overland Surges from Hurricanes (SLOSH) Model was used to develop the data. The County Storm Surge Inundation Maps and Evacuation Network Maps presented with this Study do not include riverine floodplains not subject to tidal flooding. It is assumed that local governments will use floodplain mapping (Flood Insurance Rate Maps), prepared in conjunction with the National Flood Insurance Program, for evacuation planning in non-tidal areas. Flood Insurance Rate Maps were used in this Study in the flood vulnerability analysis of public hurricane shelters.

B. Vulnerability Analysis.

Utilizing the results of the hazards analysis, the vulnerability analysis identifies those areas, populations, and facilities that are vulnerable to storm surge inundation. Evacuation

zones were developed for each of the Study Area counties utilizing major natural or man-made geographic features. Hurricane evacuation scenarios were also developed for each county. These scenarios show groups of evacuation zones that will be threatened by storm surge from specific hurricane intensity categories. Florida Department of Transportation population estimates were used in determining the vulnerable population within each county for a range of hurricane threats. These population estimates were checked against 1990 census counts as they became available. Seasonal population estimates for areas were developed with the assistance of county planning agencies and the various Chambers of Commerce.

C. Behavioral Analysis.

This analysis determines the expected response of the vulnerable population to various hurricane threat scenarios in terms of the percentage of the population expected to evacuate, probable destinations of evacuees, use of public shelter, and utilization of available vehicles. The methodology employed in the Treasure Coast Hurricane Evacuation Study to develop the behavioral data consisted of telephone sample surveys, interviews within the Study Area, data from other hurricane evacuation studies, and data from post-hurricane evacuation studies.

D. Shelter Analysis.

The shelter analysis presents an inventory of existing shelter facilities, capacities of the shelters, vulnerability of shelters to storm surge flooding, and identifies the range of potential shelter demand for each county. Lists of existing shelters and capacities were furnished by the American Red Cross and the county Emergency Management Coordinators. Lowest floor elevations for those shelters located in or near tidal or riverine inundation areas are generally established by field surveys. However, the Treasure Coast counties do not use shelters located in these low lying areas. Potential shelter demands for ranges of hurricane threats were developed using data from the behavioral analysis.

E. Transportation Analysis.

The results of all previous analyses were utilized in the transportation analysis. The purpose of this analysis is to determine the time required to evacuate the threatened population under a variety of hurricane threats. Transportation modeling techniques

developed to simulate hurricane evacuation traffic patterns were used to conduct this analysis.

COORDINATION

A. Interagency.

The Treasure Coast Region Hurricane Evacuation Study was a joint effort by the Federal Emergency Management Agency (FEMA); the National Oceanic and Atmospheric Administration (NOAA); the U. S. Army Corps of Engineers (Corps); the State of Florida, Department of Community Affairs (DCA) and the Emergency Management directors of the four counties. Development of the technical data for the study was coordinated and documented by the Jacksonville District, Corps of Engineers, in conjunction with the various Federal and State agencies and local officials in the study area.

B. Disaster Preparedness Committees.

The Disaster Preparedness Committees consisted of Florida DCA Emergency Management officials, County Emergency Management officials, and officials of other agencies and organizations, primarily at the county level, who have direct responsibility and authority in some aspect of hurricane emergency operations or planning. These officials represented agencies and organizations that included State and local law enforcement, fire departments, school boards, departments of social services, the American Red Cross, and the National Weather Service. The primary purposes of the Disaster Preparedness Committees were to provide important data for the study and to review appropriate study products. Since the committee members will be using the information generated by the evacuation study, meetings provided the forum needed to explain the methodologies and products of the various study analyses and to receive comments. Meetings were held at major milestones in the study to gather essential information, to present the results of analyses accomplished, to describe the relationships of the major analyses, and to review the progress of the study.

The Jacksonville District, Corps of Engineers had responsibility for coordinating study efforts. Direction for this study was provided by an executive committee.

C. Executive Committee.

Officials from the Florida Department of Community Affairs, Division of Emergency

Management; the Federal Emergency Management Agency; and the U.S. Army Corps of Engineers served as members of the Executive Committee. The Executive Committee convened as needed to review the progress of the study, to discuss and plan for future study tasks, and to assure the interagency coordination that was vital to the Treasure Coast Region Hurricane Evacuation Study effort.

CHAPTER TWO

HAZARDS ANALYSIS

PURPOSE

The purpose of the Hazards Analysis is to quantify the surge heights for various intensities and tracks of hurricanes considered to have a reasonable meteorological probability of occurrence within a particular coastal basin. Potential freshwater flooding from rainfall accompanying hurricanes is also addressed; however, due to the wide variation in amounts and times of occurrence from one storm event to another, rainfall can only be addressed in general terms.

The primary objective of the hazards analysis is to determine the worst-case effects from various intensity hurricanes which have the potential to strike the region. The term "worst-case" represents the peak surge height which might be obtained for each category of storm by varying three critical parameters: landfall point, direction, and forward speed. This is important to note because the maximum storm surge elevations which were mapped for the Study area were not derived from a single hurricane event. Instead, the maximum surge elevations mapped for each hurricane category represents a composite of hurricane events of varying direction, landfall point and forward speed. The potential surge is maximized by making the surge arrival coincident with the astronomical high tide (See the detailed discussion which follows on the next page). Emphasis of "worst-case" surge heights in this Analysis is justified by the purpose of hurricane evacuation planning, i.e. protection of the vulnerable population.

The majority of effort expended in the hazards analysis is related to the accurate estimation of potential surge heights. This focus on surge analysis does not reflect a discounting of the danger of winds associated with hurricanes. The magnitude, extent, timing and duration of winds of a threatening hurricane are the direct subjects of National Weather Service/ National Hurricane Center observations and forecasts. However, realistic surge height estimation is far more complex than wind speed estimation. In addition to wind speeds and direction, surge heights are also dependent on shoreline configuration, track direction, and, especially in back bay areas, on local channel geometry.

FORCASTING INACCURACIES

The "worst-case" approach was used in presenting possible hurricane effects because of the inaccuracies in forecasting the precise track and other parameters of approaching hurricanes. An analysis of hurricane forecasts made by the National Hurricane Center indicates the magnitude of error that can be expected. From 1976 to 1985, the average error in the official 24-hour hurricane track forecast was 140 statute miles left or right of the forecast track. The average error in the 12-hour official forecast was 69 miles.

During the same time period, the average error in the official 24 hour wind speed forecast was 15 miles per hour (m.p.h.), and the average error in the 12 hour official forecast was 10 m.p.h. Emergency officials should note that an increase of 10 to 15 m.p.h. can raise the intensity category of the approaching hurricane one category on the Saffir/Simpson Hurricane Scale (see Table 2-1).

POTENTIAL STORM SURGE

A. General.

Abnormally high water levels along ocean coasts and interior shorelines are commonly caused by storm events. These higher than expected water levels, known as storm surges, are generally the result of a synoptic scale meteorological disturbance. Along the mid-Atlantic seaboard, extratropical storms such as "northeasters" have produced some of the highest storm surges and resultant damages on record. However, hurricanes have the potential to produce much higher storm surges because of the vast amount of energy released by these storm systems. Storm surges can affect a shoreline over distances of more than 100 miles; however, there may be significant spatial variations in the magnitude of the surge due to local bathymetric and topographic features.

A storm surge is defined as the difference between the observed water level and the normal astronomical tide. Astronomical tides represent the periodic rise and fall of the water surface resulting from the gravitational interactions between the Moon, Sun, and Earth. Positive surges occur when the observed water level exceeds the height of the predicted

TABLE 2-1

SAFFIR/SIMPSON HURRICANE SCALE

CATEGORY 1. WINDS OF 74 TO 95 MILES PER HOUR. Damage primarily to shrubbery, trees, foliage, and unanchored mobile homes. No real wind damage to other structures. Some damage to poorly constructed signs. Storm surge possibly 4 to 5 feet above normal. Low-lying coastal roads inundated, minor pier damage, some small craft in exposed anchorage torn from moorings

CATEGORY 2. WINDS OF 96 TO 110 MILES PER HOUR. Considerable damage to shrubbery and tree foliage; some trees blown down. Major damage to exposed mobile homes. Extensive damage to poorly constructed signs. Some damage to roofing materials of buildings; some window and door damage. No major wind damage to buildings. Storm surge possibly 6 to 8 feet above normal. Coastal roads and low-lying escape routes inland cut by rising water 2 to 4 hours before arrival of hurricane center. Considerable damage to piers. Marinas flooded. Small craft in unprotected anchorages torn from moorings. Evacuation of some shoreline residences and low-lying island areas required.

CATEGORY 3. WINDS OF 111 TO 130 MILES PER HOUR. Foliage torn from trees; large trees blown down. Practically all poorly constructed signs blown down. Some damage to roofing materials of buildings; some window and door damage. Some structural damage to small buildings. Mobile homes destroyed. Storm surge possibly 9 to 12 feet above normal. Serious flooding at coast and many smaller structures near coast destroyed; larger structures near coast damaged by battering waves and floating debris. Low-lying escape routes inland cut by rising water 3 to 5 hours before hurricane center arrives.

CATEGORY 4. WINDS OF 131 TO 155 MILES PER HOUR. Shrubs and trees blown down; all signs down. Extensive damage to roofing materials, windows and doors. Complete failure of roofs on many small residences. Complete destruction of mobile homes. Storm surge possibly 13 to 18 feet above normal. Major damage to lower floors of structures near shore due to flooding and battering by waves and floating debris. Low-lying escape routes inland cut by rising water 3 to 5 hours before hurricane center arrives. Major erosion of beaches.

CATEGORY 5. WINDS GREATER THAN 155 MILES PER HOUR. Shrubs and trees blown down; considerable damage to roofs of buildings; all signs down. Very severe and extensive damage to windows and doors. Complete failure of roofs on many residences and industrial buildings. Extensive shattering of glass in windows and doors. Some complete building failures. Small buildings overturned or blown away. Complete destruction of mobile homes. Storm surge possibly greater than 18 feet above normal. Major damage to lower floors of all structures less than 15 feet above sea level. Low-lying escape routes inland cut by rising water 3 to 5 hours before hurricane center arrives.

astronomic tide. Negative storm surges (lower than expected water levels) are produced primarily in lakes or semi-enclosed basins and bays. These negative surges are considered more of a nuisance, such as a temporary hinderance to navigation, than a true natural hazard. It is the positive surge which has the greatest potential for property damage and loss of life.

There are a number of factors which contribute to the generation of storm surges but the fundamental forcing mechanism is wind and the resultant frictional stress it imposes onto the water surface. Winds blowing over a water surface generate horizontal surface currents flowing in the general direction of the wind. These surface currents in turn create subsurface currents which, depending on the intensity and forward speed of the hurricane, may extend from one to several hundred feet below the surface. If these currents are in the onshore direction, the water begins to pile up as it is impeded by the sloping continental shelf, causing a rise in the water surface. Therefore, a wide, gently sloping continental shelf is particularly conducive to the formation of large storm surges. The water level will increase shoreward until it reaches a maximum at, or some distance inland from, the shoreline. The ultimate slope of the water surface is directly proportional to the wind stress and inversely proportional to the water depth. Along the southern portion of the Treasure Coast Region the coastal areas could be affected by high waves from a severe hurricane largely due to the relatively narrow shelf. Waves are less severe and the surge is more pronounced in the northern areas of the Treasure Coast.

A secondary component of the storm surge exists when there are winds parallel to the coastline. These winds generate a current parallel to shore and, due to the Earth's rotation, the current will be accelerated to the right of the current direction (in the northern hemisphere). This is referred to as the Coriolis effect. If this current is obstructed by a coastline, the water level will begin to rise.

The reduction of atmospheric pressure within the storm system results in another surge-producing phenomenon known as the "inverted barometer" effect. Within the region of low pressure the water level will rise at the approximate rate of 13.2 inches per inch of mercury drop. This can account for a rise of one to two feet near the center of the hurricane. This effect is considered to be a more important factor in the open ocean where there is no depth related restriction to water flow.¹

¹Harris, D. Lee, 1963: U.S. Weather Bureau Technical Paper NO. 48, "Characteristics of the Hurricane Storm Surge."

Waves and swells breaking at or near the shore also cause a transport of water shoreward. During storms when there is an increase in wave height and wave steepness, water cannot flow back to the sea as rapidly as it was brought shoreward. This results in the phenomenon known as "wave setup" and causes a further increase of water level along the beachfront solely from wave action, in addition to any surge associated with the wind setup.² Waves are directly affected by the water depth and will break and dissipate their energy in shallow water. Therefore, a relatively steep offshore beachslope is particularly conducive to this process because large ocean waves can approach very near the shore before breaking.³ Wave setup is primarily a concern near the beachfront because large waves are generally not transmitted inland of the coastline even if the beach has been overtopped.

The magnitude of a storm surge within a coastal basin is governed by both the meteorological parameters of the hurricane and the physical characteristics of the basin. The meteorological aspects include the hurricane's size, measured by the radius of maximum winds; the intensity, measured by sea level pressure and maximum surface wind speeds at the storm center; the path or forward track of the storm and the storm's forward speed. The radius of maximum winds is measured from the center of the hurricane to the location of the highest wind speeds within the storm. This radius may vary from as little as 4 miles to as much as 50 miles. Due to the counter-clockwise rotation of the wind field (in the northern hemisphere) the highest surge levels are generally located to the right of the hurricane's forward track. This is particularly important when the storm makes landfall because the maximum storm surge may vary significantly within a relatively short distance depending on whether a location is to the right or the left of the path of the landfalling hurricane. The time that the storm surge arrives is important because of its potential coincidence with the time of high (astronomical) tide. Along the ocean coast of Florida's Treasure Coast Region the mean tidal range is approximately 4 feet and a surge may result in severe or only minor flooding, depending on whether it arrives at the time of high or low tide.

An estuary's overall basin geometry can attenuate or amplify a storm surge. Such factors include the basin's local bathymetry, orientation in relation to the track of an approaching hurricane, and the interior shoreline topography and configuration. An estuary in which the shoreline diverges inside the entrance will experience a decrease in the surge amplitude

² U.S. Army Corps of Engineers, Coastal Engineering Research Center, Shore Protection Manual Vicksburg, Mississippi, 1984

³Harris

toward the head of the bay. However, in a bay that converges toward the head of the estuary, a surge entering the mouth may be amplified as the shores of the bay converge. Sites located along the perimeter of a large bay may also experience localized wind and wave setups independent from the main surge due to the bay's orientation and fetch length (length of open water) relative to the hurricane's wind direction.

B. Background.

Numerous methods and models have been utilized to quantify the potential storm surge generated by hurricanes. The National Weather Service later developed computer models for specific coastal basins that account for bathymetry and other variables that affect surge heights. The most notable of these mathematical models was the Special Program to List the Amplitude of Surges from Hurricanes (SPLASH) model. Two versions of this model, SPLASH I and SPLASH II, were developed for selected basins along the Gulf and Atlantic coasts. Although the SPLASH model provides reliable still-water storm surge heights, it is rather limited in that the surge heights are calculated only for open coastlines. The latest mathematical model developed by the National Hurricane Service, the Sea, Lake, and Overland Surges from Hurricanes (SLOSH) model, is an expansion of the SPLASH model that has the capability of calculating storm surge heights within coastal sounds and estuaries as well as up rivers and creeks, while also accounting for overland surge, and taking into account terrain and barrier heights. One of the earlier guides developed for that purpose is the Saffir/Simpson Hurricane Scale, which has been adopted by the National Hurricane Center. It was developed by Herbert Saffir, Dade County, Florida, Consulting Engineer, and Dr. Robert H. Simpson, former Director of the National Hurricane Center. The Saffir/Simpson Hurricane Scale, shown in Table 2-1, is a descriptive scale which categorizes hurricanes based upon intensity, and relates hurricane intensity to damage potential. The Scale also provides a range of wind speeds and potential surge heights associated with the five (5) categories of hurricanes.

The National Hurricane Center has added a range of central barometric pressures associated with each category of hurricane described by the Saffir/Simpson scale. A condensed version of this scale with the inclusion of barometric pressure ranges by category is shown in Table 2-2.

The Saffir/Simpson Hurricane Scale assumes an average, uniform coastline for the

continental United States and was intended as a general guide for use by public safety officials during hurricane emergencies. It does not reflect the effects of varying localized bathymetry, coastline configuration, astronomical tides, barriers or other factors which may modify surge heights at the local level during a single hurricane event.

TABLE 2-2
SAFFIR/SIMPSON HURRICANE SCALE WITH
CENTRAL BAROMETRIC PRESSURE RANGES

CATEGORY	CENTRAL PRESSURE		WIND SPEED		SURGE (FEET)	DAMAGE POTENTIAL
	MILLIBARS	INCHES	MPH	KNOTS		
1	>980	>28.94	74-95	64-83	4-5	Minimal
2	965-979	28.5-28.9	96-110	84-96	6-8	Moderate
3	945-964	27.9-28.5	111-130	97-113	9-12	Extensive
4	920-944	27.2-27.9	131-155	114-135	13-18	Extreme
5	<920	<27.2	>155	>135	>18	Catastrophic

C. The SLOSH Model.

1. General.

Computer models have been developed for specific coastal basins to represent the varying bathymetry and other factors affecting surge heights calculated for a location. The Sea, Lake, and Overland Surges from Hurricanes (SLOSH) model is the latest and most sophisticated mathematical model developed to calculate potential surge heights from hurricanes. The SLOSH model was developed by the National Weather Service for real-time forecasting of surges from actual hurricanes within selected Gulf of Mexico and Atlantic coastal basins. As applied in this Study, the SLOSH model was utilized to simulate the effects of hypothetical hurricanes which could occur in the future, and to simulate actual hurricanes which have occurred in the past in the Atlantic coastal region.

The SLOSH model calculates storm surge heights for the open ocean and coastal region affected by a given hurricane. The model also calculates surge heights for bays, estuaries, coastal rivers, and adjacent upland areas susceptible to inundation from the storm surge. Significant manmade or natural barriers such as dunes, islands, etc. are represented in the model and their effects are simulated in the calculation of surge heights within the basin.

SLOSH Model coverage for the Treasure Coast Study area was provided by the model's application to the region designated as the Palm Beach Basin. The grid pattern is shown in Figure 2-1. This model was used for St. Lucie, Martin, and Palm Beach Counties. Indian River County was included in the Cape Canaveral Basin SLOSH Model.

The SLOSH model is designed for use in an operational mode; that is, for forecast/hindcast runs without controlled, local calibration, or observed winds. The rationale for this design is to avoid having the user predict unavailable input data. The SLOSH model contains a storm model into which simple, time-dependent meteorological data are input and from which the driving forces of a simulated storm are calculated. A storm event is represented by the following types of data:

- a. Latitude and longitude of storm positions at six-hour intervals for a 72 hour period, beginning 48 hours prior to landfall.

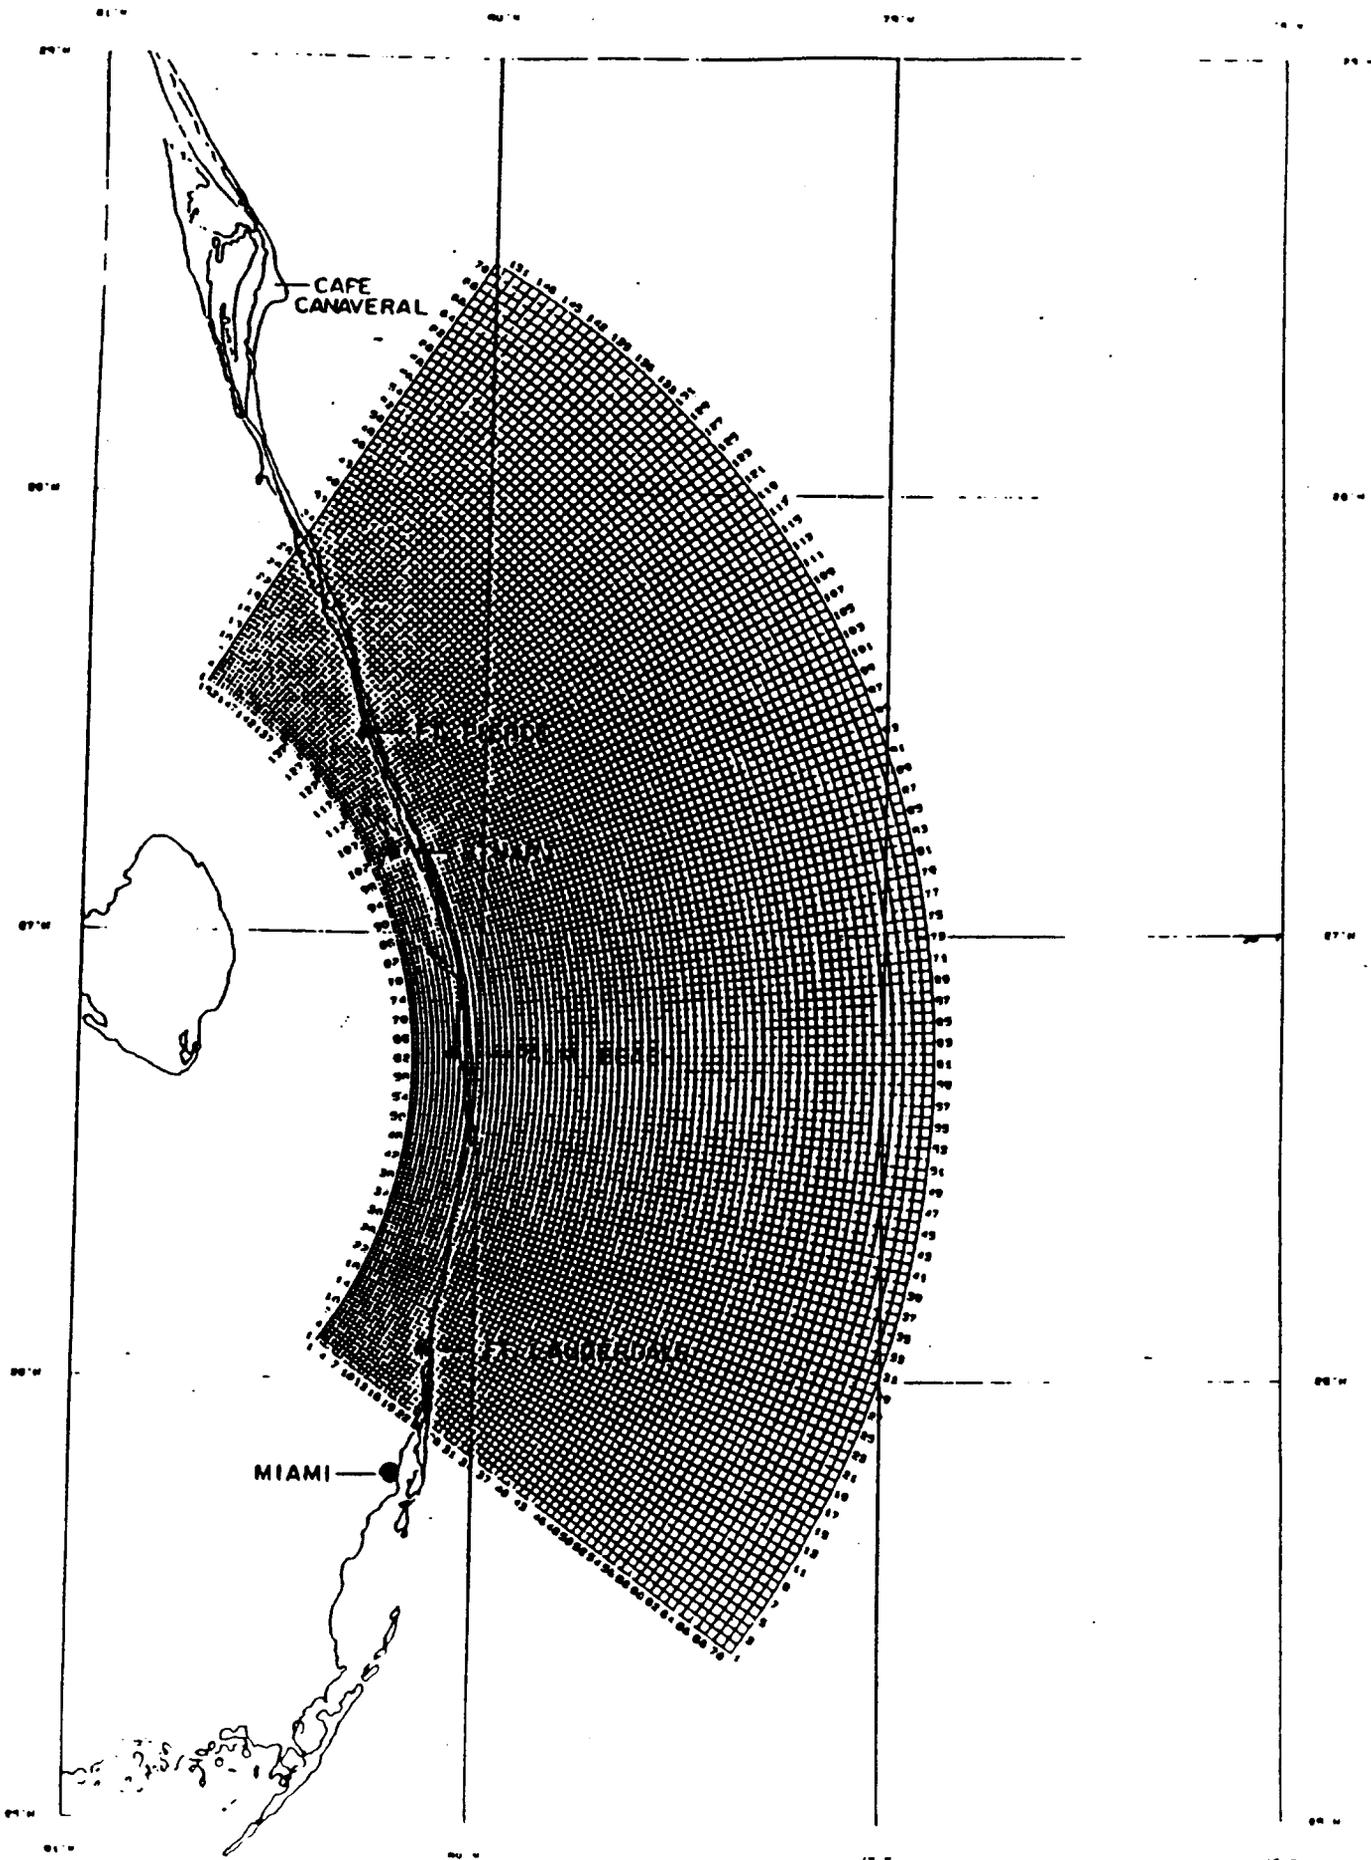

Figure 2-1 SLOSH Grid - Palm Beach Basin

- b. The atmospheric pressure at sea level in the eye of the hurricane.
- c. The storm size measured from the center (eye) to the region of maximum wind speed, referred to as the "radius of maximum wind".
- d. Forward speed of the hurricane.

The windspeeds in the hurricane are not directly input by the modeler; instead, the SLOSH model calculates the radial surface wind profile from the other meteorological parameters input by the user.

In addition, the initial height of the water surface is another parameter required to be specified by the modeler. This value is referenced to National Geodetic Vertical Datum (NGVD), the vertical datum used to specify land elevations (and water depths) within the basin. The basin was initialized with Mean High Tide data; that is, the initial water surface elevation is assumed to be higher, on the order of a foot or two, than the ordinary mean sea level for the modeled region. This increased elevation reflects the effects of the storm while it is still distant from the area of interest, typically 24 or more hours from landfall.

A summary of the SLOSH Modeling process and surge heights calculated by the Model for the Study are available in "A Storm Surge Atlas for the Palm Beach, Florida Area" prepared by the National Hurricane Center. Data for Indian River County is contained in "A Storm Surge Atlas for the Cape Canaveral, Florida Area."

Astronomical tide height fluctuations are not directly input for a given storm simulation. Instead, the SLOSH model is run with an assumed uniform starting water surface elevation, and any subsequent deviation from this level is attributable to the effects of the storm. The possible effects of the storm surge occurring at a particular phase of the tide, such as at the time of high or low tide, are evaluated as an increment, either positive or negative, to the SLOSH-predicted surge level. This topic is addressed more fully in a following section.

2. SLOSH Grid Configuration.

The SLOSH model uses a telescoping polar coordinate grid system to represent a

particular coastal region of interest. The grid developed for the Treasure Coast basin is shown in Figure 2-1. The grid consists of 71 arcs (the curved lines) and 153 radials (the straight lines). The spacing between successive arcs increases with distance from the center of the grid such that each grid cell has approximately equal length sides.

The telescoping polar grid has a number of advantages over a rectilinear grid in the efficiency of model computations. With a telescoping polar grid the area of greatest interest which in this Study is the coastal zone susceptible to hurricane surge inundation, is modeled with the highest resolution. The grid cell size is relatively smaller along the coast than the grid cell size in the deep, open water of the Atlantic. The smaller grid size allows more detailed representation of physical features, such as inlets, rivers, islands, dunes, etc., which can have important effects on the propagation of the storm surge.

Each grid square closest to the pole (at $I = 1$) represents an area of about 0.59 square miles. This permits inclusion in the model of topographic details such as highway and railroad embankments, causeways, levees, and dikes in harbors. But, with increasing distance from the pole, the range increment and arc lengths which border each grid "square" become progressively larger. At the maximum distance from the pole ($I = 71$) each grid square contains about 2.62 square miles.

The grid cell size is larger in the open ocean where less resolution of storm surge height is required. The reduced number of cells in the offshore area reduces the time and cost of each model run required. However, the larger grid cell size in the offshore region permits the inclusion of a large geographic area in the model, so that the effects of the model boundaries on the dynamics of the storm are diminished.

The characteristics of a particular basin are constructed as input data within the model. These characteristics include the topography of inland areas; river basins and waterways; bathymetry of near shore areas, sounds, bays, and large inland water bodies; significant natural and manmade barriers such as barrier islands, dunes, roads, levees, etc.; and a segment of the continental shelf. The SLOSH model simulates inland flooding from storm surge and permits the overtopping of barriers and flow through barrier gaps.

3. Verification of the SLOSH Model.

The SLOSH model was designed as an operational tool for storm surge forecasting which could be applied to any coastal area, regardless of previous hurricane history. The model's coefficients were determined using a least squares fit technique from the results of many historical hurricanes in many different basins along the U.S. Atlantic and Gulf of Mexico coastlines. Thus, the SLOSH model is not "tuned" for a particular area, other than the sense that the geometry of the region is modeled as realistically as possible. Jarvinen and Lawrence (1985)⁴ did an evaluation of the SLOSH model on ten historical hurricanes that were independent of the hurricanes used in the determination of the coefficients. The results of that study are presented below.

The performance of the SLOSH model has been evaluated using a set of 523 observations of storm-surge heights that were taken during ten hurricanes. The hurricanes made landfall in eight different basins along the U.S. Atlantic and Gulf of Mexico coastlines. Fourteen percent (14%) of the observations are tide-gage peak surge heights and the remainder are high-water marks of opportunity.

SLOSH model runs were made for each of the ten hurricanes, using all available data to determine the track and intensity input parameters. For each run, a peak-surge-height analysis was made, using the maximum computed surge height at each grid point, without regard to time of occurrence. This composite analysis, or envelope of high water, was used to determine the model surge values to be compared with the observations.

A difference between a SLOSH value and an observation was calculated for each of the 523 observations and this set of differences is the basis for an estimate of the SLOSH model error distribution. The range of the errors went from -7.1 feet to +8.8 feet. The mean error was -0.3 feet, indicating a slight negative bias. The standard deviation was 2.0 feet. Seventy-nine percent (79%) of the errors were within one standard deviation and ninety-seven percent (97%) were within two standard deviations.

Based upon the results above, a good "rule of thumb" is that the SLOSH model storm surge values will be within plus or minus twenty percent (20%) of the observed values.

⁴ "An Evaluation of the SLOSH Storm-Surge Model", Bulletin Of The American Meteorological Society, Vol. 66, No. 11, Nov. 1985.

4. Model Output.

The standard data products from a given SLOSH model run consist of both tabulated and graphical information. The tabulated output data consist of the following:

- a) User input values of storm center latitude and longitude, central pressure differential, and radius of maximum winds, at six-hour intervals.
- b) User input starting water surface elevation.
- c) Model interpolated values, at one hour intervals, of storm location (latitude and longitude), forward speed, track direction, central pressure differential and radius of maximum winds.
- d) Model computed values, at one-half hour intervals, of surge height, wind speed, and wind direction at a number of sites selected by the user. 110 sites were modeled throughout the Palm Beach SLOSH Basin. These grid sites were selected to coincide with critical locations and are generally located at low-lying roads and bridges that would be critical to an evacuation, at potentially vulnerable population centers, or at significant natural or manmade barriers. The time-history information produced by the SLOSH model for critical points lists values for still-water surge heights, wind speeds, and wind direction at 30-minute intervals for 72 hours.

The graphical data output by the model consists of a plot of the original telescoping polar coordinate grid in a rectilinear format. Each grid cell is plotted at a uniform size, which has the effect of distorting the apparent shape of the coastline and other physical features. Cells near the origin of the polar grid are thus expanded relative to their original size; cells near the outer portion of the polar grid are contracted relative to their original size.

The rectilinear plot of the model basin for a given SLOSH simulation displays the following information:

- a) The track of the hurricane being modeled.

b) The locations and names of selected geographic points.

c) The maximum water surface elevation attained at each grid cell over the duration of the storm being simulated. This plot does not represent a "snapshot" of the storm surge at an instant of time. Instead, it represents the highest water level at each grid point during a hurricane irrespective of the actual time of occurrence during that storm. This plot of maximum surge heights is referred to as the "envelope" of maximum surge for a particular storm acting on a specific SLOSH modeled basin.

The highest water level reached at each location along the coastline during the passage of a hurricane is called the maximum surge. Maximum surges along the coastline do not necessarily occur at the same time. The time of the maximum surge for one location may differ by several hours from the maximum surge at another location. The SLOSH Model printout of the surface envelope of highest surges contains the maximum surge height values calculated for each grid point irrespective of the time during the simulation that the maximum surge occurs.

D. Treasure Coast Modeling Process.

The Palm Beach Basin SLOSH model is the primary model used for the Treasure Coast Region Hurricane Evacuation Study. The Palm Beach SLOSH Basin covers the coastal region extending from just south of Melbourne, Florida, southward to Hollywood, Florida. The Cape Canaveral Basin SLOSH model was the model used for determining surge elevations in Indian River County.

1. Simulated Hurricanes.

A total of 545 hypothetical hurricanes were modeled for the Palm Beach Basin SLOSH Model. These hurricanes were specified to travel in one of five possible directions, some at one and others at two forward speeds. A range of track locations was used for each direction in order to evaluate the surge heights resulting from different storm landfall points. Storms were modeled at categories 1 through 5 of the Saffir-Simpson scale of intensity. The selection of storm parameters was based on advice of hurricane specialists at NOAA's National Hurricane Center. Table 2-3 summarizes the combinations of storm parameters which were applied in the SLOSH model of the Palm Beach Basin.

TABLE 2-3**STORM PARAMETERS FOR THE PALM BEACH BASIN**

ENE	15	1-5	13	65
E	12	1-5	13	65
TOTAL SLOSH RUNS:				545

Most hurricanes weaken after making landfall because the central pressure increases and the Radius of Maximum winds tends to increase. Modeled storms which make landfall underwent pressure increases and radius of maximum winds increases with time. A Radius of Maximum winds (RMW) of 20 statute miles was used for all category hurricanes at the point of landfall. The RMW increased to 30 miles for category 1 and 2, and increased to 25 miles for category 3, 4, and 5, twelve (12) hours after landfall. The RMW increased to 40 miles for category 1 and 2, and increased to 35 miles for category 3, 4, and 5, twenty-four (24) hours after landfall. Additional data is available in the backup material for the Hazards Analysis - Appendix B.

A total of 109 storm tracks were modeled for the Palm Beach Basin SLOSH Model. The simulated storms moving along these tracks had combinations of parameters representing the five (5) categories of hurricane intensity, as described by the Saffir-Simpson Scale. Figures 2-2 through 2-11 illustrate these storm tracks and landfall points for the ten (10) directions modeled. On the figures the hurricane symbol is at the point of landfall of the eye

of the storm, and the dots are eye positions at 6-hour increments. The tracks are identified by the distance in miles to the left side (LS) or right side (RS) of the track through Palm Beach, Florida.

Tidal anomalies of about +1 Ft MSL before arrival of a hurricane are not uncommon in the area of the basin. To simulate conditions at the time of high tide, an additional 1.5 feet of water was included for oceanic values. Inland lakes and bays, found to have a smaller tidal response, had only 1.0 feet of water added. Thus, initial ocean datums of 2.5 feet were used, while for inland lakes and bays, initial datums of 2.0 feet were used. Therefore, the resulting calculations of storm surge, using these initial datums, represent conditions at high tide.

2. MAXIMUM ENVELOPES OF WATER (MEOWS).

For a SLOSH model simulation of a discrete hurricane event, one of the data products is the plot of maximum water surface elevation at all grid cells affected by the storm, irrespective of when during the storm that maximum water level was attained. The imaginary surface defined by the maximum water level in each cell is termed the "envelope" of maximum water surface elevations for that storm. The largest individual value of water surface elevation for a particular storm is termed the "peak" surge for that event. The location of the peak surge is highly dependent upon where the storm center crosses the coastline (the landfall point). In most instances, the peak surge from a hurricane occurs to the right of the storm path and within a few miles of where the radius of maximum winds is located. This is largely due to the counter-clockwise rotation of the wind field surrounding the eye of the hurricane (in the northern hemisphere). To the right of the landfall point the winds blow toward the shoreline; to the left of the landfall point the winds blow away from the shoreline. It is important to note, however, during an actual hurricane, the least accurately predictable parameter is the point of landfall. The average error in the official twenty-four landfall position for Atlantic coast tropical cyclones over the 1970 to 1979 period was about 110 nautical miles. The average error in the 12 hour official forecast was 50 nautical miles.

Because of the inability to predict exactly where a hurricane will make landfall, and because it may be necessary to begin evacuations of areas susceptible to hurricane surges as much as 55 hours before landfall, it is necessary to predict potential surge elevations for a given hurricane over a range of potential landfall points. In order to meet this need, the SLOSH model is used to develop a map termed a "MEOW", which is the maximum envelope of water from a number of individual hurricane simulations which differ only in point of landfall of the storm center. In this manner, the maximum water surface elevations for each grid cell are calculated for a particular class of hurricane, defined by direction, forward speed, and intensity, independent of where the storm actually crosses the coastline. An example of a MEOW for a Category 3 hurricane with a 12 MPH forward speed and a northwest track direction is shown on Figure 2-12. The MEOW displays the characteristic distorted geometry which results from transforming the telescoping polar coordinate grid into a rectilinear format. The contour lines show the maximum water surface elevations at all affected points on the grid for all possible landfall points modeled.

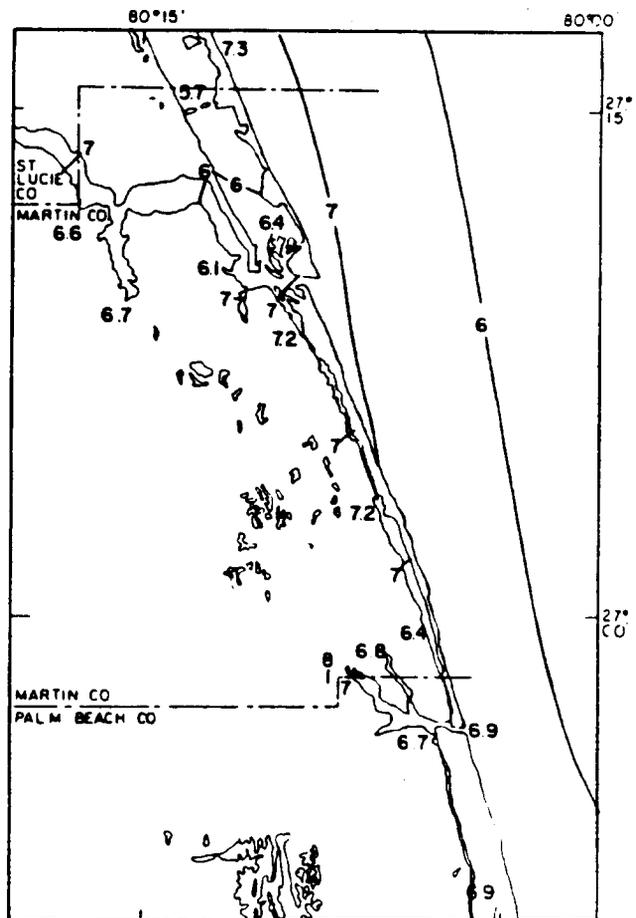

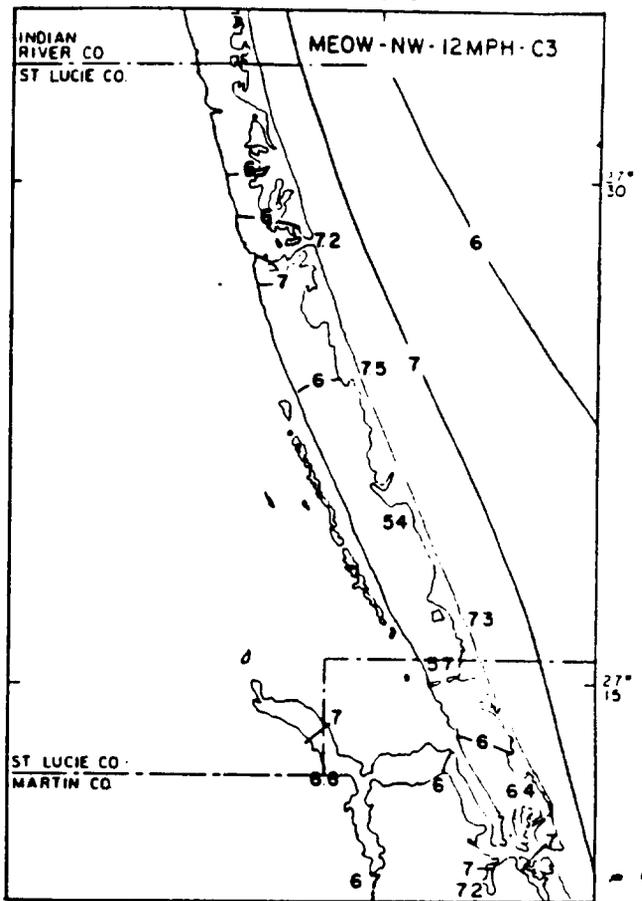

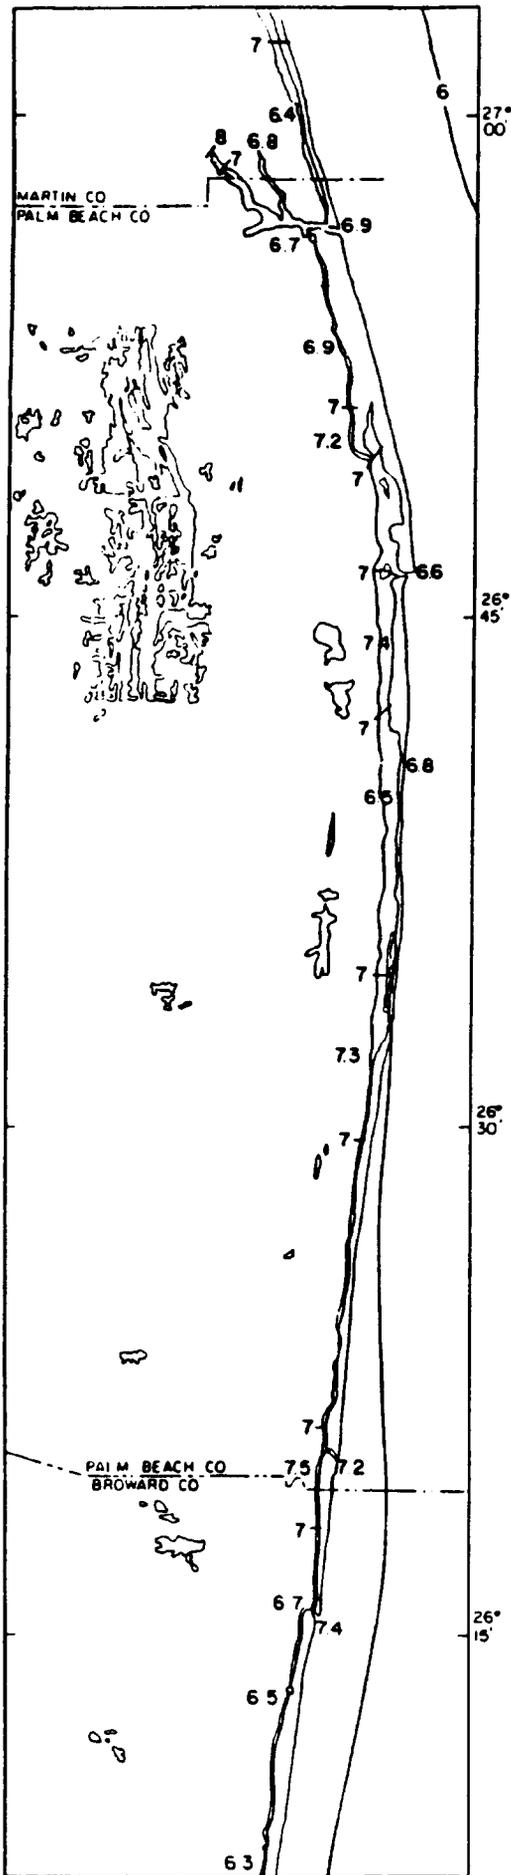

Figure 2-12

For the Palm Beach Basin, the original 545 SLOSH model runs were grouped so as to produce a total of 50 MEOWs. These 50 MEOWs were then analyzed to determine which changes in storm parameters (i.e., intensity, forward speed, direction) resulted in the greatest differences in the values of the peak surges for all locations in the modeled basin. Table 2-4 illustrates the significant differences in surge heights that result from landfall from different directions.

TABLE 2-4

**COMPARISON OF MAXIMUM COMPUTED STORM SURGE ELEVATIONS¹
AT COASTAL LOCATIONS FOR CATEGORY 5**

DIRECTION	JUPITER Bch	STUART Bch	FT. PIERCE Inlet	WABASSO Bch

NOTE: Cape Canaveral SLOSH Basin data used for Wabasso, FL in Indian River County.
Palm Beach SLOSH Basin data used for other locations.

The MEOWs were then further grouped according to overall similarities of predicted envelopes of maximum water level over the entire modeled basin. In general, it was determined that the change in storm intensity accounted for the greatest change in potential surge height for sites on the open coast. Ultimately it was determined that the 50 MEOWs could effectively be grouped into distinct classes of hurricane events defined solely by the

storm intensity. This final grouping was performed in order to provide for the development of hurricane scenarios to be used in the evacuation planning process.

3. County Storm Surge Atlases.

Areas potentially subject to flooding from Category 1, 3, and 5 hurricanes are presented for each County in maps provided with this report (County Hurricane Surge Atlases). These color portfolios were produced at a scale of 1" = 4000'. The differences in areas inundated by categories 2 and 4 were not deemed significant enough to warrant creation of separate inundation mapping. For categories 1, 3, and 5 the constituent MEOWs were evaluated to determine which MEOW produced the highest surge value for all grid cells in the Treasure Coast Region Study area. The highest surge value in each cell was then adopted to define the limits of hurricane surge inundation for each category.

Once the surge heights have been determined for the individual tracks, the maximum surge heights are plotted by storm track and hurricane category. These plots of maximum surge heights for a given storm category and track are referred to as Maximum Envelopes of Water (MEOWs). The surge inundation limits shown on the Storm Tide Atlases reflect a further composite of the MEOWs into Maximums of the Maximums (MOMs). The MOMs represent the maximum surge expected to occur at any given location, regardless of the storm track or direction of the hurricane. The only variable is the intensity of the hurricane represented by category strength. The MOM surge heights were furnished by the National Hurricane Center.

TIME-HISTORY DATA

The purpose of the time-history data is to determine the pre-landfall hazards distance for each of the counties within the Study area. Pre-landfall hazards distance is the distance from the eye of the approaching hurricane to the nearest county (or state) boundary at the time an evacuation would be curtailed due to hazardous weather. For the Treasure Coast Hurricane Evacuation Study, two conditions that could curtail hurricane evacuation were evaluated: the arrival of sustained gale-force winds (34-knot sustained wind speed, 1-minute average) and the onset of storm surge inundation of low-lying roads, bridges, or other critical areas. The first of these two conditions to occur determines the pre-landfall hazard distance.

The time of arrival of sustained tropical storm force winds is one selected goal for completing an evacuation because high-profile vehicles and vehicles pulling campers or boats could easily be overturned, especially on high bridges, by higher wind gusts accompanying those sustained winds.

Such an accident would most certainly cripple or stop traffic flow on that evacuation route. The arrival of sustained tropical force winds is also the time, under the majority of hurricane threats, when the heaviest rainfall begins. Generally, one-half of the total amount of rainfall received from a hurricane occurs from the time of arrival of sustained tropical force winds until the eye reaches the coastline.

The other condition limiting evacuation, the onset of storm surge inundation, will not be a significant factor in most of the Study area prior to the arrival of sustained tropical force winds. Storm surge is the increase in height of the surface of the sea due to the forces of the approaching hurricane. At all 110 SLOSH time-history points the arrival of sustained tropical force winds occurs before the onset of storm surge inundation and, therefore, determines the pre-landfall hazards distance. Evacuation decision making officials should be aware that the coincidence of high astronomical tide with storm surge could cause moderate flooding at low-lying critical points prior to the arrival of sustained tropical force winds.

Since the limiting factor for hurricane evacuation used in this Study is the arrival of sustained tropical force winds, the pre-landfall hazards distance for any county can be defined as the distance to the eye of the approaching hurricane upon the arrival of sustained tropical force winds, or, more simply stated, the radius of sustained tropical force winds of the threatening hurricane. Thus, for the Treasure Coast Hurricane Evacuation Study area, the pre-landfall hazards distance and the radius of sustained tropical force winds are synonymous.

Since the windfields of actual hurricanes can vary significantly from one to another as well as within the same hurricane over time, the observed and forecasted radii of tropical storm winds generated by the National Hurricane Center should be used. This information is contained in the Marine Advisory.

Marine advisories, produced by the National Hurricane Center every 6 hours, give the measured distance in nautical miles of the 34-knot (approximately 40 miles per hour),

1-minute sustained wind speed from the eye of an approaching hurricane. These distances are given for the four quadrants of a hurricane (i.e., northwest, northeast, southeast, southwest). Forecasts of these distances for 12, 24, 48, and 72 hours into the future are also given. The largest measured distances of the radius of 34-knot, 1-minute sustained winds should be used for evacuation decision-making. Further discussion of the application of the radius of tropical force winds to hurricane evaluation decision-making is contained in Chapter 7, Decision Arcs.

Generic radii of tropical storm winds that can be obtained from the SLOSH model time history points should not be used for decision making purposes!

WAVE EFFECT

The SLOSH model does not provide data concerning the additional heights of waves generated on top of the still-water storm surge. Generally, waves do not add significantly to the area flooded by storm surge and can usually be ignored except for locations immediately along the open coastline or the shorelines of very large bays and estuaries where significant fetch (open water) lengths and water depths may exist. Since nearshore wave phenomena under hurricane conditions are not well understood, it is assumed that for the open coast, maximum theoretical wave heights based upon relationships of fetch length to water depth will occur near the time of landfall. Wave heights can be expected to be approximately 55% of the surge depth. Due to the presence of structures, dunes, or vegetation, the waves break and their energy dissipates within a few hundred yards of the coastline.

It is perhaps more important for evacuation planning purposes to consider potential wave effects for less than sustained tropical force wind speeds. The rationale here is to determine if wave action above still-water surge heights will exceed the elevations of roads, bridges, or other critical areas near the coastline, thereby increasing the pre-landfall hazards distances.

Before making calculations of wave height and run-up at critical locations within the Study area, surge heights at the time of arrival of sustained tropical force winds should be considered. A review of the SLOSH time histories show that maximum surges at critical points within the Study area at the time of arrival of tropical force winds are on the order of 3.0 feet or less. Since tides of this magnitude are experienced fairly routinely without major

traffic problems, calculations of wave height and runup were not made; however, evacuation planners should be aware that low-lying sections of some highways could be subject to inundation from wave action prior to the arrival of sustained tropical force winds. This would be especially true with the occurrence of high astronomical tides.

FRESHWATER FLOODING

Amounts and arrival times of rainfall associated with hurricanes are highly unpredictable. For most hurricanes, the heaviest rainfall begins near the time of arrival of sustained tropical force winds; however, excessive rainfall can precede an approaching hurricane by as much as 24 hours. Unrelated weather systems can also contribute significant rainfall amounts within a basin in advance of a hurricane. Due to the unpredictability of rainfall from hurricanes, no attempt was made to employ sophisticated modeling or analysis in quantifying the effects of rainfall for the Treasure Coast Hurricane Evacuation Study area. Areas and facilities which have historically flooded during periods of heavy rainfall are assumed to be vulnerable to freshwater flooding under hurricane threats. Additionally, evacuation planners should be aware of the possibility of rainfall induced ground saturation, which may increase the possibility of trees being overturned, causing road obstructions, power outages, traffic light failures, etc. The Flood Insurance Studies published by FEMA for municipalities within the Study area should be consulted for specific potential freshwater flooding information.

CHAPTER THREE

VULNERABILITY ANALYSIS

PURPOSE

The primary purpose of the vulnerability analysis is to identify the areas, populations, and facilities which are vulnerable to flooding associated with hurricanes. The storm surge data from the hazards analysis were used to map inundation areas, in order to determine evacuation zones and evacuation scenarios for each of the Study area counties; to quantify the population at risk under a range of hurricane intensities; and to identify major medical/institutional and other facilities that are potentially vulnerable to storm surge.

Mobile homes are the only type of housing specifically addressed in the analysis of populations vulnerable to hurricane winds. No attempt was made to identify other housing particularly vulnerable to wind damage. Throughout the region a significant mobile home population living outside the potential hurricane surge areas adds dramatically to the number of hurricane vulnerable people in the area. The Transportation Model Support Document (Appendix E) lists the number of permanent dwelling units, mobile homes, and seasonal units by county and evacuation zone.

HURRICANE EVACUATION ZONES

a. General.

Through the hazards analysis, those areas which will receive hurricane storm surge were identified and graphically shown on the County Storm Surge Atlases. This information became one of the key inputs to the transportation analysis. Residents who must evacuate were defined.

It was assumed that persons living in areas flooded by storm surge should be

evacuated. This evacuee group included permanent residents living in single-family, multi-family, or mobile home units, as well as tourists staying in hotel/motel, condominium, and time share seasonal units located in storm surge vulnerable areas. In addition, mobile home residents living outside the hurricane flooded areas of each county were assumed to evacuate due to high wind vulnerability.

Having identified those areas which should evacuate during a particular storm event, a series of zones to geographically locate and quantify the vulnerable population were developed. Evacuation zones also provide a base to model traffic movements from one geographic area to another. A series of zones was established for each county based on the following factors:

- Zones should relate to expected surge flooding to expected surge flooding limits (based on Maximum Envelope of Water - MEOWs) for each storm scenario.
- Zones should relate well to census, traffic analysis zones, or other data base unit.
- Zones should be set up, if possible, for ease of use in issuing an evacuation order or advisory.
- Zonal boundaries should include identifiable natural features, roadways, landmarks, etc.
- Small "pocket" zones that would be isolated by surrounding surge should be avoided.
- Zones should be able to be served by major evacuation routes.
- Zones should have relatively balanced population levels.
- Zones must allow for appropriate transportation modeling.

Evacuation zones have been developed for each of the four (4) counties in the Treasure Coast Region Hurricane Evacuation Study. Each of the evacuation zones are delineated as much as possible using major natural or manmade geographic features and conform to existing political or demographic boundaries (i.e., census tracts or traffic analysis zones) within the county. The purpose of this delineation is to aid in the development of population data to be used in traffic modeling; to determine sheltering requirements; and to facilitate

future updating.

There were 31 Evacuation Zones established for Indian River County; 29 for St. Lucie County; 41 for Martin County; and, 53 for Palm Beach County. More data on the Evacuation Zones and their assumed vulnerability is contained in Chapter 6 - Transportation Analysis.

b. Zone Descriptions.

Zone descriptions and delineations are shown on the Traffic Evacuation Zone Maps in Chapter 6.

HURRICANE EVACUATION SCENARIOS

a. General.

Hurricane evacuation scenarios have been developed for each of the four counties in the Study area. The evacuation scenarios are groups of evacuation zones that will be threatened by storm surge from specific hurricane intensity categories. In many instances, the same evacuation zones are threatened by a range of intensity categories. In those cases, the zones requiring evacuation have been combined into evacuation scenarios based on combinations of hurricane intensities.

b. County Scenarios.

Storm scenarios developed for each of the Study area counties are shown in Table 6-1. Table 6-2 contains the hurricane evacuation scenarios and lists the evacuation zones comprising each scenario. The storm scenarios are also shown in Table 3-A. These scenarios are illustrated on County Evacuation Zone maps, Figures 6-2 through 6-6.

VULNERABLE POPULATION

The vulnerable population within each of the Study area counties is comprised of those persons residing within the evacuation zones subject to storm surge, as well as the residents of mobile homes located elsewhere in the county. Due to their greater vulnerability to the strong winds associated with hurricanes mobile home residents are included in calculations of vulnerable population. The wide spread wind destruction from Hurricane Andrew has forced us into considering other modest or weak structures to be vulnerable as well. The potential tourist population, based on the number of occupied tourist units, is also included in the population of each evacuation zone. Table 3-1 lists the vulnerable population for each of the hurricane evacuation scenarios based on 1990 population data.

INSTITUTIONS/MEDICAL FACILITIES

Inventories of institutions/medical facilities have been compiled for each of the Study area counties. The purpose of this analysis is to identify facilities which may require evacuation, or may have access affected under various hurricane threats. Lists of major institutions/medical facilities in or near inundated areas are presented in Tables 3-2 through 3-5. An evaluation should be made for each facility to determine actual susceptibility to flood damage from localized drainage problems and special flood hazard areas, as well as from surge. It would be advisable to evaluate the potential damage to be expected from winds for all special facilities. The general locations of the facilities are given in the tables. Public shelter locations are given in Chapter 5.

NOTES

- ¹ County is developing software to provide a more complete listing of medical facilities and institutions.
- ² Part of the City of West Palm Beach is within the designated 100-year flood plain (elevation: 12-16 ft. NGVD); additional portions of the City are potentially subject to inundation [see Palm Beach County Hurricane Storm Surge Maps].
- ³ For a detailed assessment of potential flood vulnerability, lowest floor elevations should be compared to flood elevations determined by the FIS for the NFIP (100 yr. flood elevation: 12-16 ft. NGVD in some areas) and maximum surge elevations calculated by the SLOSH Model [see Palm Beach County Hurricane Storm Surge Map].

CHAPTER FOUR

BEHAVIORAL ANALYSIS

PURPOSE

The behavioral analysis is intended to provide reliable estimates of how the public in the Study Area will respond to a variety of hurricane threats. The estimates include the percentages of persons in specific locations that can be expected to evacuate, when they will evacuate relative to an evacuation advisory, and where they will seek shelter. These estimates are utilized in establishing assumptions to be used in other Study analyses and for guidance in emergency decision-making and public awareness efforts.

OBJECTIVES

The primary objective of the Treasure Coast Region Hurricane Evacuation Study behavioral analysis was to provide public evacuee response data for use in the shelter analysis and the transportation analysis. It also provides for guidance in emergency decision-making and public awareness efforts. The specific objectives of the Behavioral Analysis were to determine the following:

- a. The percentages of the affected and non-affected population that will evacuate under a range of hurricane threat situations or in response to evacuation advisories. The term "affected population" refers to those persons residing near the coastline, the shorelines of estuaries, or in areas of low elevation near those locations that are subject to the hazards of flooding. The affected population also includes those persons residing in mobile homes or substandard housing which may be at risk from the winds associated with a hurricane. The term "non-affected population" refers to those individuals who are not threatened by storm surge or freshwater flooding and have substantial housing affording protection against winds expected to occur during a hurricane. It is known that a number of these non-vulnerable individuals evacuate

along with the vulnerable population and contribute to the evacuating traffic and shelter demand during a hurricane threat.

- b. When the evacuating population will leave in relation to an evacuation advisory given by local officials or other persons of authority.
- c. The number of vehicles that the evacuating population will use during a hurricane evacuation.
- d. The percentage of the total number of evacuating vehicles which may be towing boats, camper trailers, or other vehicular equipment.
- e. The probable destinations of evacuating households. These data consist of percentages of the total number of evacuees going to local public shelters, staying locally with friends or relatives, staying locally in a hotel/motel, or leaving the county for out-of-region destinations.
- f. How the threatened population will respond based upon forecasts of hurricane intensity, probability, or other information provided during a hurricane emergency.
- g. The evacuation responses of tourists.

DATA SOURCES

The primary data source for the Treasure Coast Hurricane Evacuation Study was the Report, "Behavioral Assumptions for Hurricane Evacuation Planning in the Treasure Coast Region," February 1993. The report relied on a reanalysis of data originally collected for an earlier report prepared in 1983. In addition, a follow-up report was produced - "Post-Andrew Behavioral Analysis for Hurricane Evacuation Planning in the Treasure Coast Region of Florida," October 1993. Both reports were produced for the Study by Hazards Management Group, Inc. These reports are included as Appendices to this report.

A. Sample Surveys.

The February 1993 report included survey findings about public response in Indian River, St. Lucie, and Martin Counties during Hurricane David in 1979, as well as hypothetical response data from those counties. It also utilized survey data collected in Palm Beach County as part of the Southeast Florida behavioral analysis prepared in 1990.

B. Hypothetical Responses from Other Areas.

Much hypothetical response data has been collected, but it can rarely ever be used literally for quantitative forecasts. It does have some utility when carefully used, however. There are certain biases in hypothetical response data, which can be adjusted to account for those known biases.

Actual response data from many hurricane evacuations spanning a wide geographical area has been amassed by Hazards Management Group. They have recorded a variety of hurricane threat circumstances over a period of roughly three decades. Their General Response Model has been used successfully in evacuation plans along the Gulf and Atlantic coasts, including the Treasure Coast region in 1988, and was enhanced by surveys conducted after Hurricane Andrew measuring public response.

C. Post-Hurricane Response Studies.

A survey was conducted in 1982 to document how Treasure Coast residents responded during Hurricane David in 1979 (Treasure Coast Regional Planning Council, 1983). Data from that survey is cited and compared to responses normally observed in similar circumstances in the February 1993 Behavioral Analysis report. The 1982 survey asked Treasure Coast residents what they would do in future hurricanes. Those hypothetical responses will be compared to what people actually did in David, to other hypothetical surveys, and to responses indicated by the General Response Model.

The extreme destruction caused by Hurricane Andrew in south Dade County prompted concerns about how that storm might affect future response in the Treasure Coast region. The report titled "Post-Andrew Behavioral Analysis for Hurricane Evacuation Planning in the Treasure Coast Region of Florida," October 1993, addresses this concern and documents actual response to a recent major hurricane in the region. Actual response data is, of course, the most useful in making projections about future evacuation behavior.

Although the studies show social variations from place to place, there are greater variations in public response between different hurricane threats in the same location than there are between similar events in different locations. Also, attempts to detect response differences along socio-economic lines among residents of a given location have generally

been inconclusive. These findings permit considerable confidence in applying conclusions drawn in one location to similar situations in another area.

ANALYSIS RESULTS

A. General.

The following paragraphs address each of the specific objectives established for the behavioral analysis and present generalized results for each objective. More detailed information is contained in the Behavioral Analyses included as Appendix C to this report.

B. Evacuation Participation Rates.

There are two overriding factors influencing whether residents evacuate: actions by public officials and degree of hazard of the location. In floodprone areas near the open coast, 90% or more of the residents will evacuate if public officials take aggressive action urging or ordering evacuation and are successful in communicating the urgency of that message. The only way to ensure that the message reaches the intended audience is to supplement television and radio announcements with police or other officials going into neighborhoods door-to-door or at least with loudspeakers. Less aggressive or less successful dissemination of evacuation notices will result in evacuation rates could be perhaps 25% lower in high and moderate risk areas.

The risk area categories shown in Table 4-1 do not generally correspond to the coastal, middle, and interior areas used in the 1982 survey. High risk areas refer to barrier islands and open coast, which are about the same as the 1982 survey's coastal zone. Moderate risk areas refer to areas that would flood in most hurricanes, but are not in the open coast. Flood depths and wave action would be less severe than in high risk areas. These would include the most hazardous parts of the 1982 middle area. Low risk areas are normally subject only to hurricane winds.

TABLE 4-1
Evacuation Rates for Planning

Severe Storm Evacuation Ordered in High and Moderate Risk Areas and Mobile Homes			Weak Storm Evacuation Ordered in High Risk Areas Only and All Mobile Homes		
RISK AREA					
<u>High</u>	<u>Moderate</u>	<u>Low</u>	<u>High</u>	<u>Moderate</u>	<u>Low</u>
Housing other Than Mobile Homes					
90%+	75%	15%	85%	40%	10%
Mobile Homes					
95%	90%	80%	90%	75%	65%

C. Response Rates.

Evacuee response rates refer to the rate of evacuation by the threatened population and when the evacuating residents will leave relative to a given evacuation advisory. These rates are expressed as cumulative percentages of the total number of evacuees departing at time intervals before and after an evacuation advisory. Evacuation response rates for Hurricane Andrew are discussed and shown in Appendix C, Behavioral Analysis.

Post-hurricane response studies show a diversity of slopes and shapes inherent in the response curves. This diversity can be primarily attributed to factors such as actions by local officials, severity of the hurricane, residents' perception of the probability of the storm striking their location, and the evacuation difficulties for their location. The primary factor consistent with most of the historic response curves is the sharp increase in evacuation response following the advice of local officials to evacuate. These increases in evacuation response following local advisories show consistency regardless of location, relative magnitude of the threat, or information previously furnished to the threatened population in the form of hurricane watches, warnings, or other meteorological information.

Further information on evacuee response rates is contained in Chapter 6, Transportation Analysis.

D. Vehicle Use.

Not all available vehicles are used when a household evacuates because there is concern about separating the family in traffic. The percentages of vehicle use developed for the Treasure Coast Region Hurricane Evacuation Study are based on previous experience and telephone sample surveys conducted as part of the study. These surveys included hypothetical responses, as well as actual percentages from the Hurricane Andrew evacuation.

It would be reasonable to assume, based on survey results, that 70% to 75% of available vehicles would be used in an evacuation. Additional information on transportation use can be found in Appendix C, Behavioral Analysis.

E. Destinations of Evacuating Households.

One of the most difficult evacuation behaviors to predict is the percentage of evacuees who will leave the local area. This is because it tends to vary so much from one region to another.

The destinations or types of refuge most commonly used by the evacuating population are local public shelter facilities, local friends or relatives, local hotels/motels, or out-of-county locations. Significant variation in the percentages of persons utilizing various types of refuge can occur. Historically, this has occurred from storm to storm as well as from location to location.

Table 4-2 shows the expected rates of evacuees who would be expected to seek refuge outside the county.

TABLE 4-2
Evacuees Going Out of County

Severe Storm Early Evacuation			Weak Storm Typical Timing		
RISK AREA					
<u>High</u>	<u>Moderate</u>	<u>Low</u>	<u>High</u>	<u>Moderate</u>	<u>Low</u>
60%	45%	40%	50%	40%	25%

**Note: A last minute evacuation would result in lower rates.
Lower income areas would be 10 percentage points lower.**

The actions of local officials can influence the sheltering rates within a county. If, for example, public shelters are opened early and advertised, the public shelter use rates will most likely be significantly higher than for areas where the public is strongly advised to leave the county or where shelter locations and availability are not widely advertised.

Additional information on destinations of evacuees is contained in Appendix C, Behavioral Analysis.

F. Evacuation Response of Vacationers.

The behavior of tourists is one of the most difficult to predict. Some feel that most tourists will leave prior to the start of an evacuation of permanent residents. Others feel that tourists might take a "wait and see" attitude, resulting in a significant number of tourists present during an evacuation.

This uncertainty was addressed by developing a low and a high occupancy rates of 50% and 85% for use in clearance time data. Further information is contained in Chapter 6, Transportation Analysis.

CHAPTER FIVE

SHELTER ANALYSIS

PURPOSE

The shelter analysis serves two primary purposes. The most apparent use of analysis data is to determine the number of evacuees who will seek public shelter (shelter demand) within each county and to determine the number of spaces available for those evacuees. This is the public shelter demand/capacity analysis. Total shelter capacity for each county is subject to change with the availability of suitable facilities.

The second purpose of the shelter analysis is to provide part of the information needed to determine evacuation clearance times in the Transportation Analysis. This is done by establishing the locations of shelters and their vulnerability. A thorough discussion of the methodology involved in those determinations may be found in Chapter Six.

This shelter analysis presents a list of shelters, capacities, shelter demand, as well as considering potential flood vulnerability of the public shelters. Data developed in the hazards, vulnerability and behavioral analyses were used in this shelter analysis.

SHELTER ANALYSIS

A. General.

It is important to note that a listing in this report does not indicate that a facility will be used in a given hurricane evacuation. The choice of public shelters for a specific evacuation is an operational decision. Shelters will be opened by county and municipal authorities based on a variety of circumstances including season, intensity and direction of the threatening hurricane, and availability of qualified people, including American Red Cross (ARC) personnel, to manage facilities. Additionally, available public shelter space will

change as buildings are constructed or demolished, as ownership changes and as agreements are reached or cancelled with building owners and with the ARC. The recent (July 1992) publication of hurricane shelter selection guidelines by the Red Cross may precipitate revisions of shelter lists.

B. Inventories and Capacities.

Tables 5-1 through 5-4 list ARC and county operated public shelters and capacities, provided by County emergency management directors. No attempt has been made, at this time, to assess the vulnerability of the public shelters to the effects of hurricane force winds. The locations of the public shelters are also given in Tables 5-1 through 5-4.

C. Vulnerability.

When using information contained in this study to evaluate the safety of a shelter, inaccuracies in hurricane forecasting and modeling should be taken into account. It might be considered, as a safety factor, that planners base their evaluation of potential storm surge flooding for each hurricane category on the next higher category surge levels (see Chapter 2, Forecasting Inaccuracies).

No public shelters are located in a Storm Surge area.

Local emergency management officials are urged to examine all shelters to determine if any are obviously unstable.

PUBLIC SHELTER DEMAND & CAPACITY

A. General.

The results of the Behavioral Analysis conducted for the Treasure Coast Region Hurricane Evacuation Study were used in determining the shelter demand for a variety of hurricane scenarios. The shelter capacities used in the analysis were developed by County and American Red Cross officials.

² American Red Cross. "Yes" indicates that the ARC has agreed to operate the facility as a hurricane shelter.

³ 1st floor elevations are National Geodetic Vertical Datum (NGVD), which is comparable to mean sea level, and were provided by County officials.

B. Public Shelter Demand.

Table 5-5 shows the public shelter demand (number of evacuees seeking public shelter) resulting from each evacuation scenario. Evacuation scenarios are defined for each county in Chapter 6, Table 6-1. Since seasonal occupancy varies, shelter demand is given based on that variation. The analysis assumes an adequate warning period for an approaching hurricane and sufficient public knowledge concerning the locations and availability of public shelter facilities. Other assumptions used in developing the total number of evacuees and public shelter demand are as follows:

1. One hundred percent of the affected population will evacuate. (This assumption is incorporated into the Shelter Analysis and the Transportation Analysis even though the Behavioral Analysis indicates that participation rates in most hurricanes will be somewhat less than 100 percent.)
2. One to five percent (depending on storm intensity) of nearby non-affected population will evacuate.
3. Persons living in highly vulnerable locations (Category 1), especially on the shoreline, will utilize public shelter facilities at rates of 10 to 15 percent of the total number of evacuees from those locations.
4. Persons living in moderately vulnerable locations (Category 2-3) will utilize public shelter facilities at a rate of 15 to 20 percent of the total number of evacuees from those locations.
5. Forty to forty-five percent of the mobile home residents and persons evacuating from areas of low vulnerability will utilize public shelter facilities.
6. Less than five percent of vacationers are expected to seek public shelter.

C. Public Shelter Capacity.

Except for Martin County, shelter capacity is not reduced for the various storm scenarios, since there are no designated shelters located in surge areas. Martin County has six (6) shelters in the Category 5 surge area. Providing capacity in addition to the American Red Cross (ARC) shelters has little affect on clearance times. However, additional capacity would result in a reduction in the number of evacuees seeking shelter in nearby counties.

D. Public Shelter Analysis.

The results of the public shelter capacity analysis is shown in Tables 5-1 through 5-4. The table contains the total public shelter capacity within each county as discussed in paragraphs B and C above.

CHAPTER SIX

TRANSPORTATION ANALYSIS

PURPOSE

During a hurricane evacuation effort, a large number of vehicles have to be moved across a road network in a relatively short period of time. The number of vehicles and evacuees becomes particularly significant for an area such as the Treasure Coast region of Florida, where several significant urban areas and beach communities are located. The magnitude of evacuating vehicles varies depending upon the intensity of the hurricane, presence of seasonal residents, and certain behavioral response characteristics of the vulnerable population.

Vehicles enter the road network at different times depending on the evacuee's response relative to an evacuation order or advisory. Conversely, vehicles leave the road network depending on both the planned destinations of evacuees and the availability of acceptable destinations such as public shelters, hotel/motel units and friends' or relatives' homes in non-flooded areas. Vehicles move across the road network from trip origin to destination at a speed dependent on the traffic loadings on various roadway segments and the ability of the segments to handle a certain volume of vehicles each hour.

The overall goals of the transportation analysis performed for the Treasure Coast Hurricane Evacuation Study were to estimate clearance times (the time it takes to clear a county's roadway of all evacuating vehicles), to define the evacuation road network, and to look at general traffic control issues that could affect traffic flow along critical roadway segments. Clearance time is a value resulting from transportation engineering analysis performed under a specific set of assumptions. It must be coupled with pre-landfall hazards data to determine when a strong evacuation advisory must be issued to allow all evacuees time to reach safe shelter before the arrival of sustained tropical storm winds. Pre-landfall hazards include sustained tropical force winds and/or roadway inundation prior to landfall of the eye. Factors that influence clearance time must be studied intensively to determine which factors have the strongest influence. Therefore, a sensitivity analysis was performed and a range of clearance times calculated for each county by varying key input parameters.

The transportation analysis task initially identified the kinds of traffic movements associated with a hurricane evacuation that must be considered in the development of clearance times. Basic assumptions for the transportation analysis were then developed related to storm scenarios, population-at-risk, behavioral and socioeconomic characteristics, the roadway system and traffic control. A transportation modeling methodology and a roadway system representation were developed for each county in the study area to facilitate model application and development of clearance times. General information and data related to the transportation analysis are presented in summary form in the Technical Data Report. A Transportation Model Support Document is available through the Jacksonville District Corps of Engineers and includes detailed transportation modeling statistics and zone by zone data listings for each county.

EVACUATION TRAVEL PATTERNS

The movements associated with hurricane evacuation have been identified for the purposes of this analysis by five general patterns:

A. In-County Origins to In-County Destinations

Trips made from primarily storm surge vulnerable areas and mobile home units in an individual county to destinations within the same county, such as public shelters, hotel and motel units, and friends or relatives outside the storm surge vulnerable areas.

B. In-County Origins to Out-of-County Destinations

Trips made as in Item A (described above) that originate in an individual county but have destinations in other counties of the study area or outside the study area entirely.

C. Out-of-County Origins to In-County Destinations

Trips made as in category A that enter an individual county from other counties in the study area.

D. Out-of-County Origins to Out-of-County Destinations

Trips passing through an individual jurisdiction while traveling from one county in the study area to another or outside the study area entirely. This travel pattern is

particularly significant due to the effects of lower southeast Florida traffic passing through the Treasure Coast region during an evacuation.

E. Background Traffic

Trips made by persons preparing for the arrival of hurricane conditions; these trips may be shopping trips to gather supplies and/or trips from work to home to assist the family in evacuation. This traffic can also include transit vehicles (vans/buses) used to pick up evacuees without personal transportation.

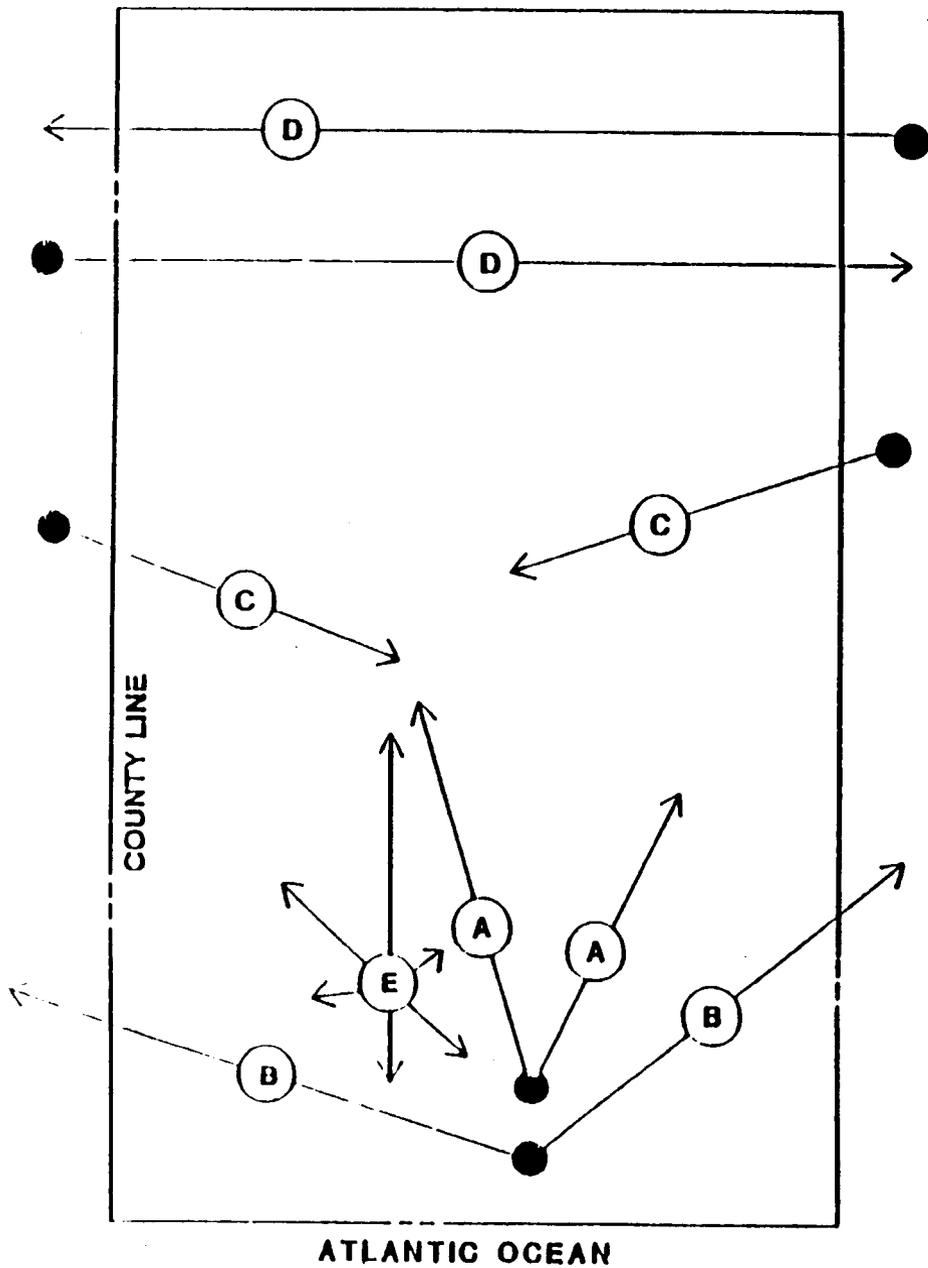

Figure 6-1 graphically depicts these traffic movement patterns associated with hurricane evacuation situations in the Treasure Coast region. It is important to recognize that three of the five defined patterns involve traffic movement patterns generated outside of one county's boundaries. It is evident that, depending on the assumed storm track, these inter-county movements resulted in a number of regional traffic impacts. During the transportation analysis task, these movements were quantified to facilitate estimation of demand for roadway segment and resulting clearance times.

TRANSPORTATION ANALYSIS INPUT ASSUMPTIONS

Since all hurricanes differ from one another in some respect, it becomes necessary to set forth clear assumptions about storm characteristics and evacuees' expected response before transportation modeling can begin. Not only does a storm vary in its track, intensity and size, but also in the way it is perceived by residents in potentially vulnerable areas. These factors cause a wide variance in the behavior of the vulnerable population. Even the time of day at which a storm makes landfall influences the time parameters of an evacuation response.

The transportation analysis results in clearance times based on a set of assumed conditions and behavioral responses. It is likely that an actual storm will differ from a simulated storm for which clearance times are calculated in this report. Therefore, a sensitivity analysis was performed during the transportation modeling. Those variables have the greatest influence on clearance time were identified and then varied to establish the logical range within which the actual input assumption values might fall.

EVACUATION TRAVEL PATTERNS

- Ⓐ In-County Origins To In-County Destinations
- Ⓑ In-County Origins To Out-Of-County Destinations
- Ⓒ Out-Of-County Origins To In-County Destinations
- Ⓓ Out-Of-County Origins To Out-Of-County Destinations
- Ⓔ Background Traffic

Figure 6-1

Key assumptions guiding the transportation analysis are grouped into five areas.

1. Permanent and Tourist Population Data
2. Storm Scenarios
3. Evacuation Zones
4. Behavioral Characteristics of the Evacuating Population
5. Roadway Network and Traffic Control Assumptions

These five areas and their assumed parameters are described in the following paragraphs. Those parameters which were varied for sensitivity analysis are noted.

Permanent and Tourist Population Data

The data base for each county was developed using 1990 census and traffic analysis zonal data provided through the Florida Department of Transportation District 4 office. This source of data provided a base for permanent population parameters on a sub-county basis. Since data are regularly updated for traffic analysis zones and census units, their use provides a means to facilitate updating of the evacuation study in the future.

Seasonal and permanent dwelling unit data assembled by Post, Buckley, Schuh & Jernigan, Inc. included the following resources:

- U.S. Census Bureau - 1990 Population and Housing Units
- Various Chamber of Commerce and travel bureaus
- Florida Department of Transportation, District 4 - 1990 Traffic Analysis Zonal data

Any future update of the transportation analysis should take a careful look at the seasonal dwelling unit data in the sub areas of each county. Numbers for seasonal units were generally a combination of hotel/motel units and other units listed as seasonal in nature by the U.S. Census.

Current permanent population estimates range from approximately 93,000 in Indian River County to 900,000 in Palm Beach County. Throughout the region a significant mobile home population living outside the potential hurricane surge areas adds dramatically to the number of hurricane vulnerable people in the area. The Transportation Model Support Document (Appendix C) lists the number of permanent dwelling units, mobile homes, and seasonal units by county by evacuation zone and TAZ (or census unit).

Storm Scenarios

The hazards analysis identified those storm tracks (Reference pages 2-18 to 2-27) causing the worst possible and probable storm surge in each county of the study area for each of five hurricane intensity categories (corresponding to the Saffir-Simpson scale). When five storm intensities are factored by several varying behavioral parameters, the number of hypothetical hurricane situations can quickly reach a great number. Calculation of clearance times for a great number of storm situations would be cumbersome and unusable by local emergency preparedness officials and would be inappropriate given the relative level of accuracy of hurricane storm forecasting. Storm forecasting for the period 12 to 24 hours prior to eye landfall is generally not precise enough to allow for more than 2 or 3 storm scenarios (grouping by intensity) per county.

Census tracts and traffic analysis zones (where appropriate) were compared with storm surge limits corresponding to the five hurricane categories. This procedure identified where major differences in storm surge limits and number of vulnerable population exist relative to each progressive step in hurricane intensity. Table 6-1 provides the storm scenarios developed in the transportation analysis for each county.

Evacuation Zones

Through the hazards analysis, those areas which will receive hurricane storm surge were identified and graphically shown in the County Storm Tide Atlases. This information became one of the key inputs to the transportation analysis. Those residents who must evacuate as well as those residents who should not evacuate were defined.

TABLE 6-1
Transportation Analysis Storm Scenarios

<u>County</u>	<u>Storm Scenario</u>	<u>Saffir-Simpson Category</u>
Indian River	A	Cat. 1-2
	B	Cat. 3-5
St. Lucie	A	Cat. 1-2
	B	Cat. 3-5
Martin	A	Cat. 1-2
	B	Cat. 3
	C	Cat. 4-5
Palm Beach	A	Cat. 1-2
	B	Cat. 3
	C	Cat. 4-5

Within the transportation analysis it was assumed that persons living in areas flooded by storm surge should be evacuated. This evacuee group included permanent residents living in single-family, multi-family, or mobile home units, as well as tourists staying in hotel/motel, condominium, and time share seasonal units located in storm surge vulnerable areas. In addition, mobile home residents living outside the hurricane flooded areas of each county were assumed to evacuate due to high wind vulnerability.

Having established those persons who should evacuate during a particular storm situation, it was then necessary to develop a series of zones to geographically locate and quantify the vulnerable population. Evacuation zones also provide a base to model traffic movements from one geographic area to another. A series of zones was established for each county based on the following factors.

- Zones should relate to expected surge flooding to expected surge flooding limits (based on Maximum Envelope of Water - MEOWs) for each storm scenario.
- Zones should relate well to census, traffic analysis zones, or other data base unit.
- Zones should be set up, if possible, for ease of use in issuing an evacuation order or advisory.
- Zonal boundaries should include identifiable natural features, roadways, landmarks, etc.
- Small "pocket" zones that would be isolated by surrounding surge should be avoided.
- Zones should be able to be served by major evacuation routes.
- Zones should have relatively balanced population levels.
- Zones must allow for appropriate transportation modeling.

Table 6-2 provides the number of evacuation zones for the transportation analysis and assumed vulnerability of each zone for storm scenarios in each county of the study area. Number of zones range from 29 zones in St. Lucie to 53 zones in Palm Beach County.

TABLE 6-2

		B	3	1-19	20-53
		C	4-5	1-24	25-53

Figures 6-2 through 6-6 illustrate the evacuation zones established in each county for the transportation analysis.

Behavioral Assumptions

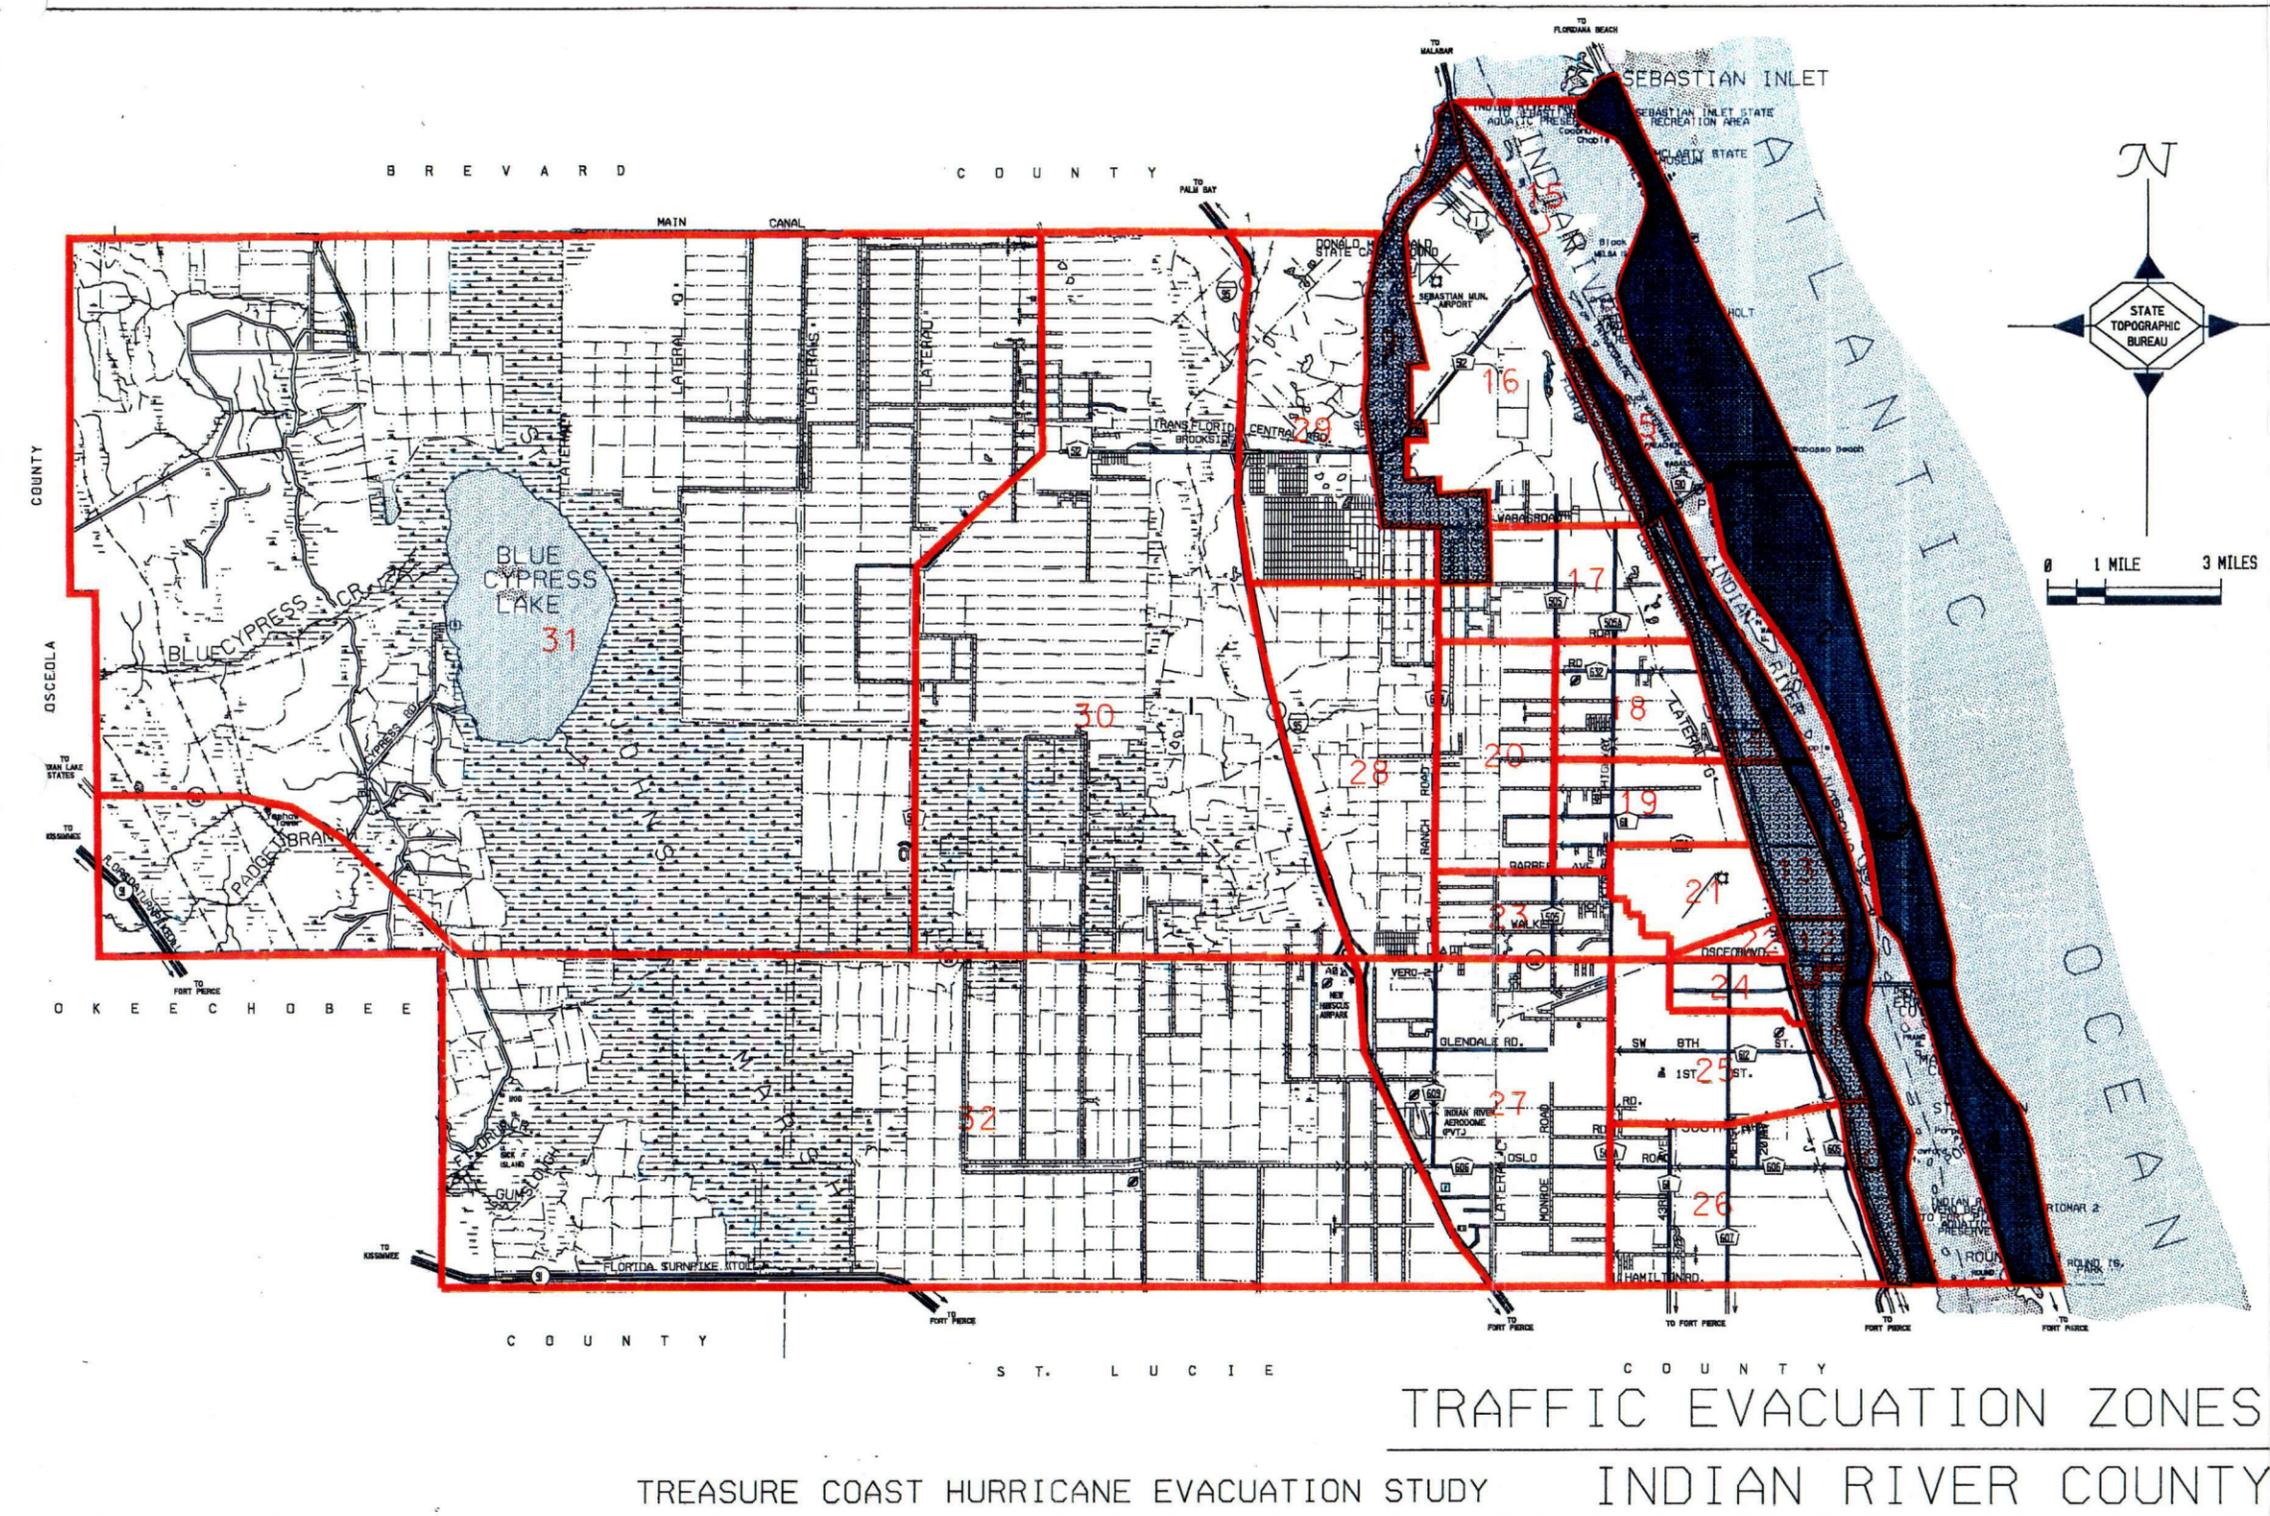

Recognizing that the future evacuation of an vulnerable population due to a hurricane approaching the Treasure Coast study area involves the coordinated action of thousands of individuals, the Hazards Management Group gathered detailed information through a behavioral analysis pertaining to the tendencies and intended plans of the evacuation population. A traditional behavioral analysis was accomplished and then followed by a later behavioral analysis which focused on identifying the impact Hurricane Andrew would have on future evacuations.

PBS&J reviewed these data to derive the best assumptions possible for the transportation analysis. Specifically, for transportation purposes, the following behavioral aspects were addressed:

- Occupancy of seasonal units
- Participation rates
- Evacuation rates (rapidity of response)
- Destination desires
- Vehicle usage

As a hurricane approaches the study area the number of seasonal residents who may be required to evacuate along with the permanent residents could be significant. Discussions at workshop meetings with disaster preparedness officials along the eastern seaboard have revealed a number of varying opinions regarding this issue. Some individuals feel strongly that most tourists will leave prior to the start of an evacuation of permanent residents. Others feel that tourists might possibly take a "wait and see" attitude, resulting in a significant number of tourists present at the start of an evacuation.

To address these differing opinions, and to develop clearance time data related to two levels of season occupancy, a low and high occupancy percentage of 50 and 85% was

applied to total seasonal units in each county. These variations can be used for occupancies related to summer versus late fall seasonal characteristics.

Another important aspect is that of participation rates. Several elements were incorporated in the transportation analysis regarding participation in the evacuation. At the request of local emergency management officials, participation rates of those residing in surge flooded zones were assumed to be 100%. A 100% participation by those evacuees living in mobile homes outside the surge flooded areas was also assumed. In addition, a small percentage (1 to 5% depending on storm intensity) of the "non-vulnerable" population was assumed to evacuate their dwelling units in the counties. An additional "Post Andrew" participation rate scenario was incorporated where in addition to the 100% surge and mobile home assumption, 10 to 25% of the other residents were assumed to participate. The Transportation Model Support Document provides a listing of all participation rates assumed by storm scenarios for each county in the study area.

A critical behavioral aspect that must be considered for the transportation analysis is the evacuation rate of the evacuating population. Behavioral data from research of past hurricane evacuation shows that mobilization and actual departures of the evacuating population occur over a period of many hours and sometimes several days. For the Treasure Coast study, clearance times were tested for three to four evacuation response rates (depending on the area) represented by different behavioral response curves. Behavioral response curves describing mobilization by the vulnerable population define the rate at which evacuating vehicles load onto the evacuation street network for each hourly interval relative to an evacuation order or strong advisory. The percentage of evacuees leaving dwelling units is then available for the calculations relating to traffic loadings at critical links along the evacuation network. The behavioral response curves shown in Figure 6-7 range from rapid response to extra-long response and are intended to include a potential range of possible mobilization times that might be experienced in a future hurricane evacuation situation. For sensitivity analysis, the mobilization/traffic loading time was varied between four hours and twelve hours.

BEHAVIORAL CUMULATIVE EVACUATION CURVES

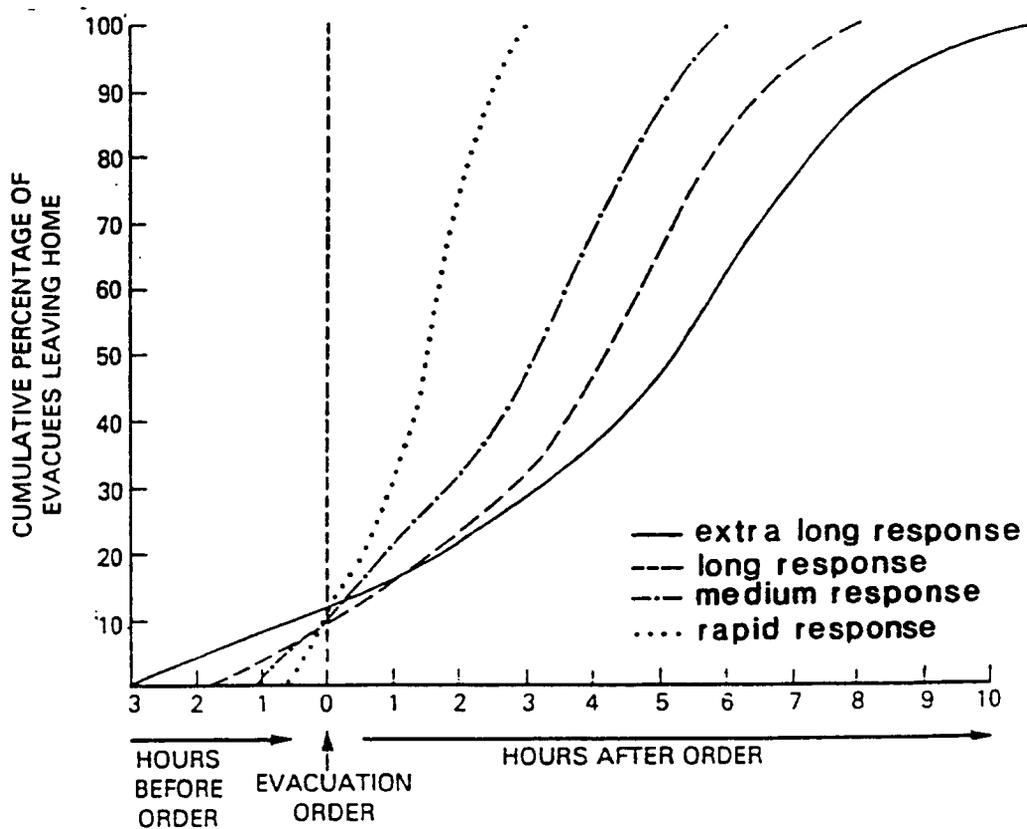

Figure 6-7

The percentage of evacuees assumed to go to one of four general destination types was another important behavioral input to the transportation analysis. Evacuee destination percentages were discussed with emergency management staff in each area after careful review of information available in past behavioral research. Figures were developed for the expected percent of evacuees going to public shelters, hotel/motel units, the home of a friend or relative, or out of the county entirely. Destination percentages were varied for each evacuation zone in each county depending on category of risk (distance from coastline) or special characteristics of a zone such as high number of substandard housing units or low income residents. Specific assumptions for each scenario and evacuation zone are provided in the Transportation Model Support Document. It should be noted that these destination percentages refer to destination desires. Where destination desires could not be satisfied with in-county capacities, the transportation analysis assumed that these evacuees would have to leave the county to find acceptable shelter.

A final behavioral assumption refers to vehicle usage and the percent of households expected to pull a trailer or recreational vehicle during an evacuation. Review of the behavioral survey and discussions with local officials produced the needed parameters. Vehicle usage percentages refer to the percentage of vehicles available at the home origin that are assumed to be used in the evacuation. Vehicle usage percentages were approximately 70% to 80% (depending on distance from the coastline) for the Treasure Coast study transportation analysis. The percent of households expected to pull a boat, trailer or RV was approximately 1-5 percent in the immediately coastal area zones.

Roadway Network and Traffic Control Assumptions

A final group of assumptions used for input to the transportation analysis is related to the roadway system chosen for the evacuation network and traffic control measures selected for traffic movement. Although the assumptions developed for the transportation analysis are general, the efforts at county and municipal levels regarding traffic control and roadway selection must be quite detailed. Detailed manpower allocations to major intersections, interchanges, and bridges involve extensive coordination among local and state officials. This study does not presume to replace those efforts, but seeks to quantify the time elements within which such manpower would operate.

In choosing roadways to be used for the evacuation network, an effort was made to

include street facilities with sufficient elevations, little or no adjacent tree coverage, substantial shoulder width and surface, and roadways already contained in existing hurricane evacuation plans. Another objective was to include east-west arterials and bridge combinations that would provide the smoothest (least disjointed) possible traffic flow.

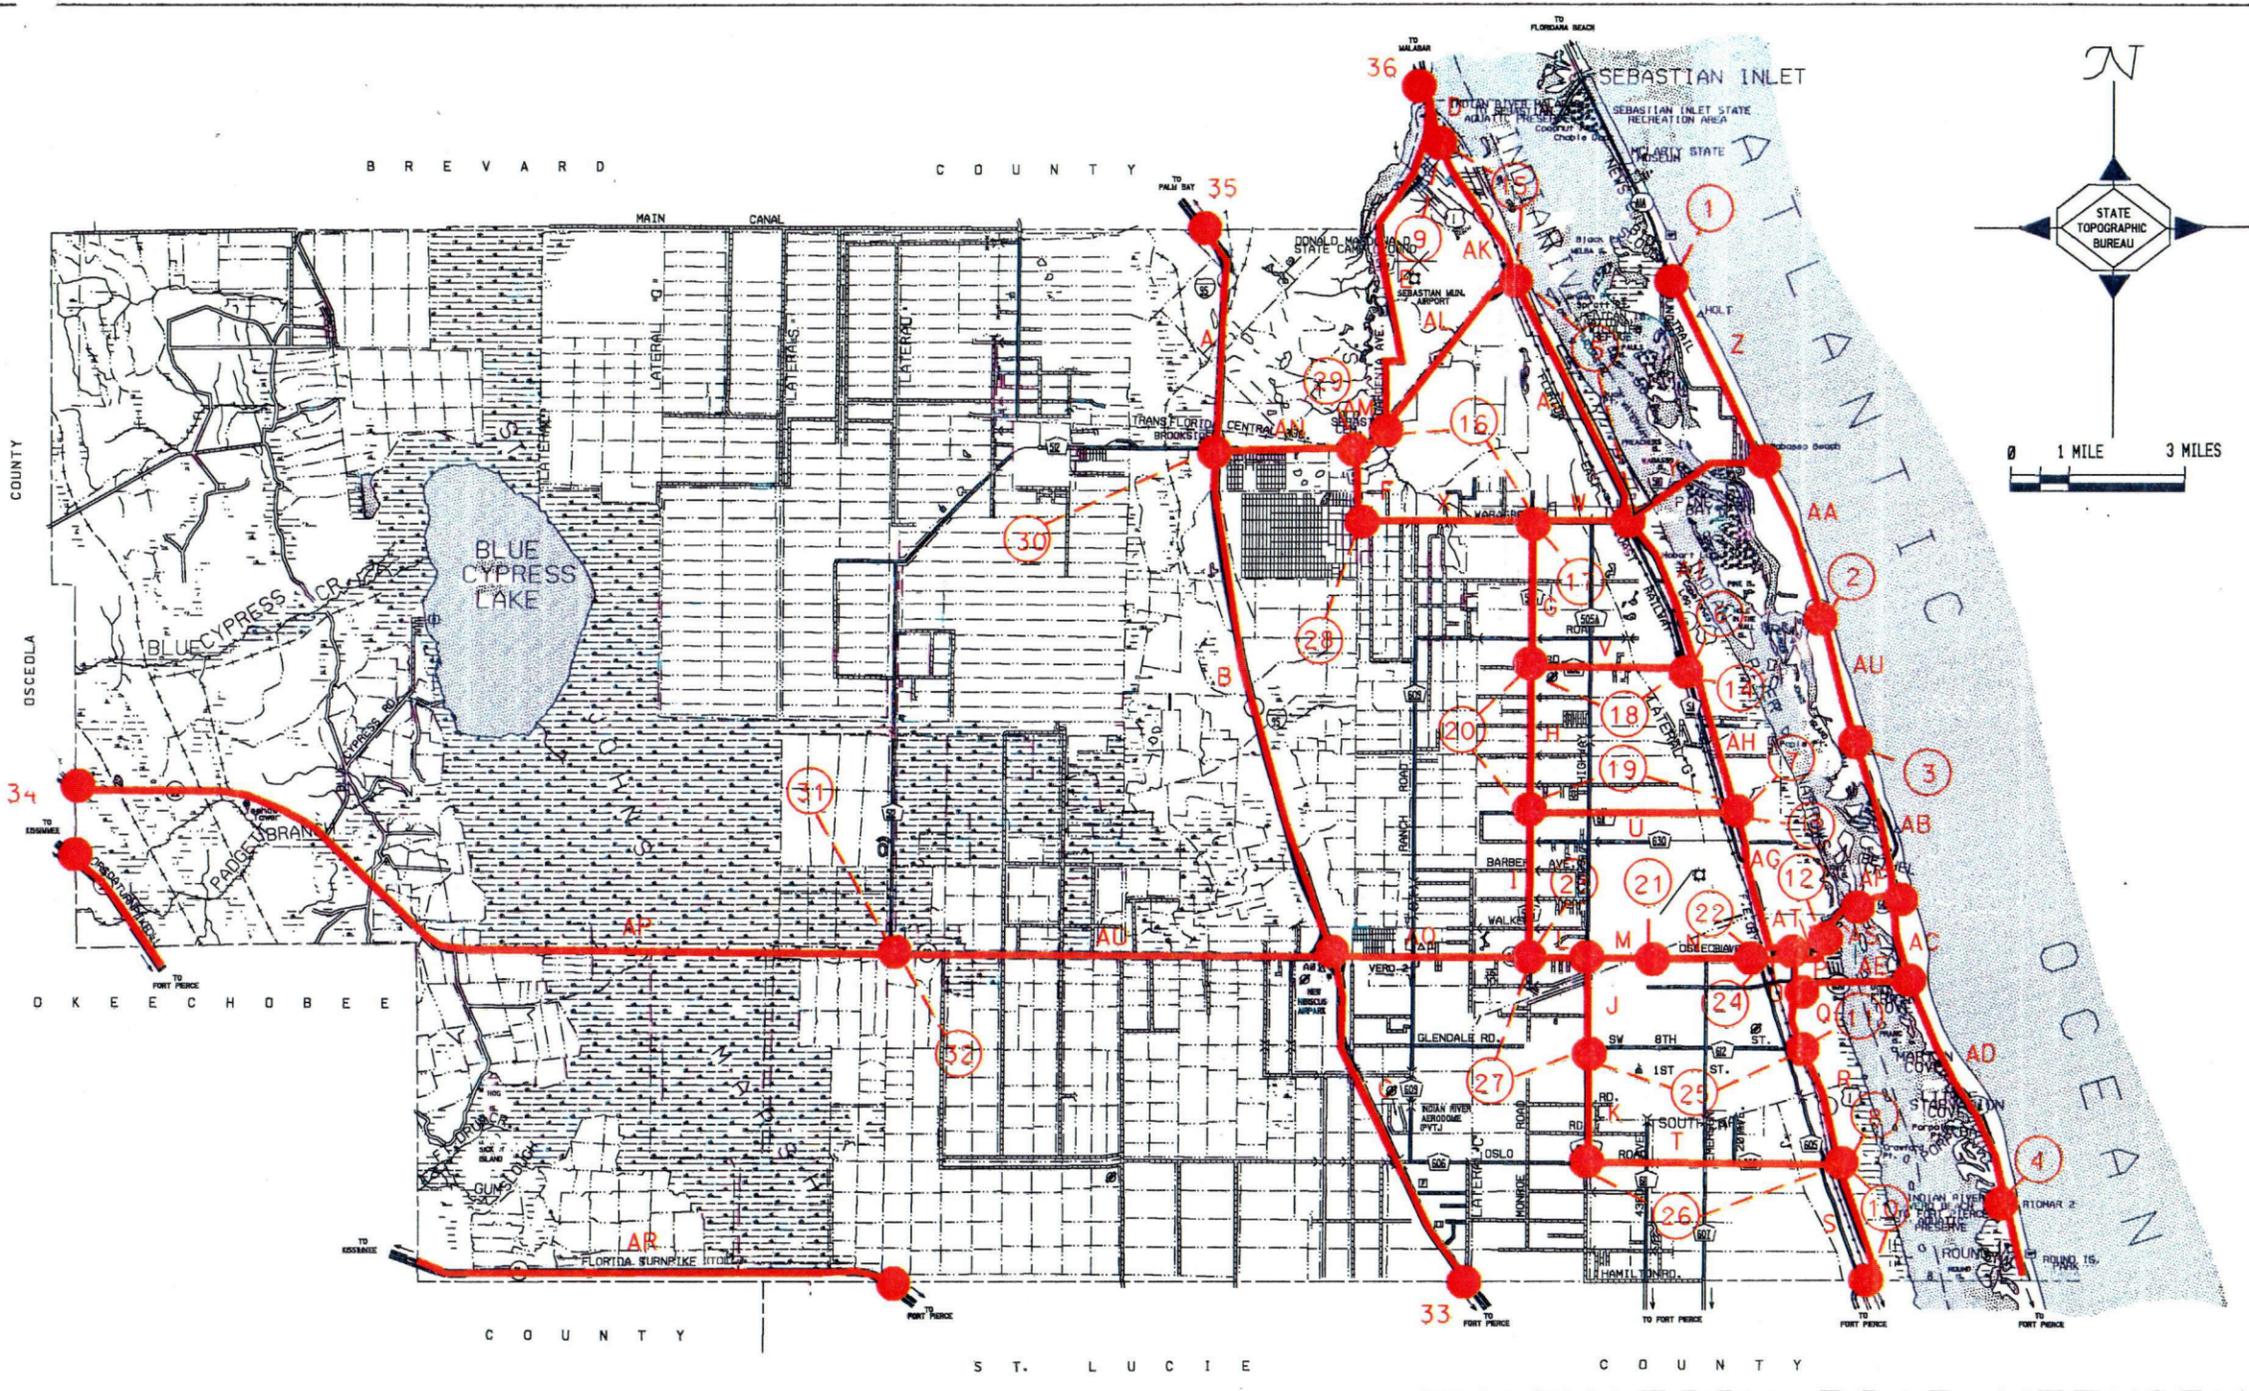

In order to determine the routing of evacuation a representation of the roadway system was developed. A traditional "link-node" system was developed to identify roadway sections. Nodes are used to identify the intersection of two roadways or changes in roadway characteristics. Links are the roadway segments as defined by the nodes when connected. Each link is identified by a letter designation.

Once the links and nodes for the evacuation routes were identified, roadway characteristics were specified for each link. The characteristics of each link were defined by the following features.

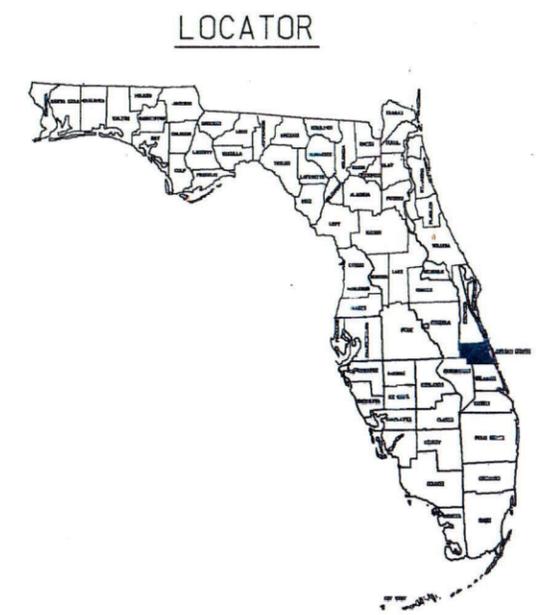

- Number of travel lanes
- Type of facility

Figures 6-8 through 6-12 show the roadway system representations (evacuation networks) for each county in the study area. The significance of link node segments and zone connectors (dashed lines) is explained in the Transportation Model Support Document. The figures consist of base maps showing all the major streets in the study area with identification of the nodes and centroid connectors in color. Detailed roadway link information is contained in the Transportation Model Support document.

An important assumption for the transportation modeling was that all drawbridges would be locked down and open to vehicular traffic during a Hurricane Warning period. U.S. Coast Guard regulation 33-117.1(c) may give Civil Defense authorities the ability to

implement this procedure. At the present time, request for closure prior to a major disaster occurring (and prior to the warning period) should be directed to the U.S. Coast Guard. The U.S. Coast Guard has the capability of acting on these requests immediately. It is essential that appropriate bridge regulations be interpreted and implemented to allow for immediate response to an evacuation order. It may be prudent in some areas for boat owners to find safe harbor prior to a or during a Hurricane Watch period. The lives of citizens evacuating in vehicles could be at risk if bridges are not allowed to operate at near full capacity during a Hurricane Warning. Bridges openings obviously result in less than full hourly capacity for vehicular movement.

It was assumed that special personnel (state police, local policemen, sheriffs, deputies), will be assigned to critical intersections in the study area. This would allow for smoother traffic flow and would allow east-west traffic movements more intersection "green time." The transportation modeling task also assumes that provisions would be made for removal of vehicles in distress during the evacuation.

Assumptions concerning the road network are that the evacuation of all vehicles will occur prior to the arrival of sustained tropical storm winds (39 mph) and storm surge inundation.

In summary, data inputs to the transportation analysis can be classified into one of four categories:

- Hazards Data
- Socioeconomic Data
- Behavioral Data
- Roadway Network

Table 6-3 provides a listing of each major data input for each of the four categories.

OVERVIEW OF TRANSPORTATION MODELING METHODOLOGY

The work tasks involved in performing the transportation analysis are illustrated in Figure 6-13. In addition to the front end development of population data, evacuation zones, and

WORK FLOW DIAGRAM

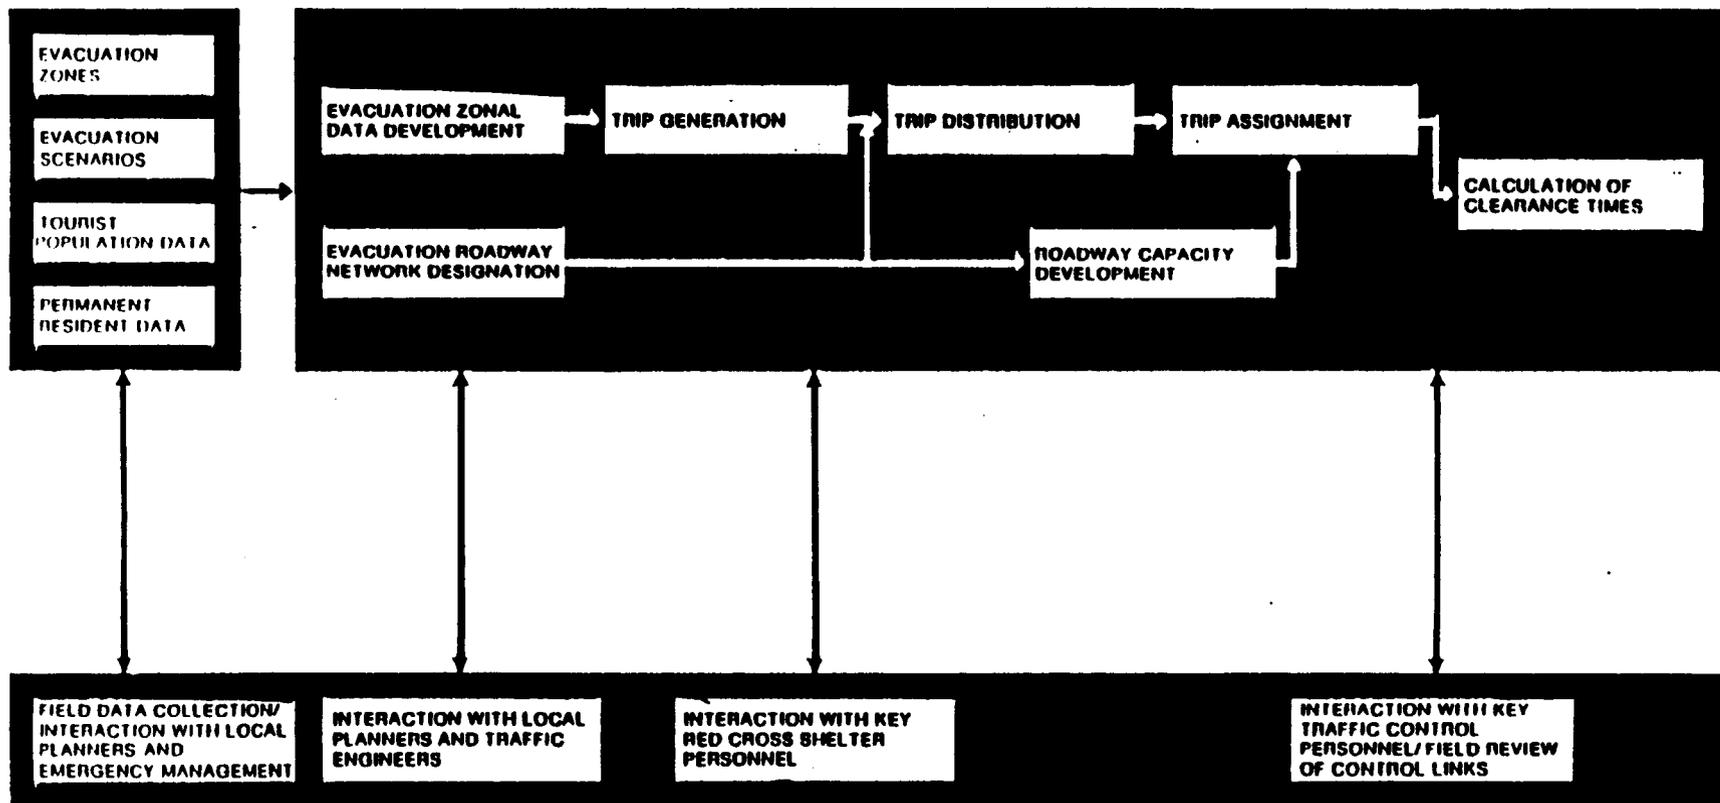

Figure 6-13

scenarios, the diagram provides the transportation modeling steps in the upper right hand box.

The transportation modeling methodology developed and employed for the Treasure Coast study area involved a number of manual and computer techniques. The methodology, while very technical, was designed to be consistent with the accuracy level of the modeling inputs and assumptions. The methodology is unique in that it is sensitive to the key behavioral aspects of evacuees.

The Transportation Model Support document specifies and explains the steps carried out in the transportation modeling at a detailed technical level. In summary, the modeling methodology involved seven major steps. These steps are briefly described below:

1. **Evacuation Zonal Data Development** - Data gathered by census tract/traffic analysis zone were stratified by evacuation zone. Numbers of permanent residential dwelling units, mobile homes, and seasonal units were compiled by zone and formatted for input into trip generation.
2. **Evacuation Road Network Preparation** - This step involved developing information for those roadways selected for inclusion in the evacuation road network. Information was coded into a "link file" for use by the assignment computer module. The end product of the step was a computerized representation of the roadway system.
3. **Trip Generation** - Specific dwelling unit variables were used in the trip generation calculations to produce total evacuating people and vehicles originating from each evacuation zone. Originating vehicles and people were stratified by destination type based on behavioral and population parameters previously established. Hotel/motel information coupled with public shelter capacity information were used to develop estimates of the number of evacuating vehicles that would find acceptable destinations in each zone.
4. **Trip Distribution** - This step concentrated only on those trip originating in a county and finding acceptable destinations within the same county. Productions from each zone were matched with available attractions in all zones. The end product of the step was a trip table showing trips between each zone and all other zones for each evacuation destination type. A unique trip table was developed for each storm scenario and for each tested behavioral assumption. Trip tables were also produced for trips originating in a county and leaving the county at assumed exit points.

5. **Roadway Capacity Development** - Number of lanes and facility type information for each roadway link in the evacuation network were translated into a level of service D directional hourly service volume for comparative purposes. Specific hourly flow rates were then developed for the most critical roadway segments and intersections.
6. **Trip Assignment** - this step included the use of another computer program to assign zone to zone trips onto the roadway system. All other categories of evacuation travel patterns (out-of-county to in-county, out-of-county to out-of-county, and background) were then added to arrive at total evacuation vehicles per roadway segment. This step then developed a series of volume to service volume ratios to determine which roadway segments would be most congested by evacuation vehicles. Those links with the highest volume to service volume ratios were identified for each county.
7. **Calculation of Clearance Times - Travel Time/Queuing Delay Analysis** - this step involved a detailed look at the critical links and intersections identified for the four counties of the study area. Initially, evacuation zones using the critical link of interest were identified. Evacuation vehicles from each zone were then released to the network in accordance with a behavioral response curve. Based on an assumed hourly flow rate for the critical link, the hourly volume desiring to use the link was then translated into a queuing delay time at the link and an evacuation travel time. The end product of this major step was a set of clearance time for each storm scenario.

MODEL APPLICATION

Application of the transportation modeling methodology produced several key data items for hurricane evacuation planning and preparedness. Completion of the transportation modeling produced the following:

1. Evacuating people and vehicle parameters
2. Shelter demand and capacity considerations
3. Traffic volumes and critical roadway segments
4. Estimated clearance times

Although many pieces of information are produced in the transportation analysis, these data items are most critical to planning shelter needs, addressing traffic control issues, and defining the timing requirements of an evacuation.

Evacuating People and Vehicle Parameters

Using a computer process, total evacuating vehicles and people produced by each zone were split by destination type (public shelter, hotel/motel unit, friend or relative's home, or out of the county). This was accomplished for each storm scenario and further refined by assumed behavioral characteristics of the population-at-risk. The Transportation Model Support Document provides this trip generation data for the zones of each county.

Table 6-4 provides ranges of evacuating people and vehicles for each county within the study area. The number of people evacuating and vehicles expected to be utilized in hurricane evacuations varies due to the effect of testing different storm scenarios and behavioral parameters. Figures are based on current census and TAZ population and previously discussed behavioral aspects of vulnerability areas relating to the SLOSH Maximum Envelope of Water limits for all hurricane directions and speeds. It is important to remember evacuating people figures include mobile home residents and a small percentage of person who will evacuate although theoretically not vulnerable. Mega Participation rates assume 100% of surge area homes, 100% of mobile homes and 10-25% of others evacuate.

Shelter Demand/Capacity Considerations

While the data discussed above are extremely important, they are most useful when matched with available sheltering. It is important to note that evacuating people and vehicle statistics generated for each county, evacuation zone, and destination type reflect where evacuees would go assuming enough safe destinations were available. After matching evacuee's destination desires with available shelters, the transportation analysis revealed that hotel/motel space will not be as widely available within the study area as perceived by the evacuating population. For transportation modeling purposes, those evacuees unable to be accommodated by study area hotel/motel space were assumed to find hotel/motel space outside the study area.

Table 6-5 provides the calculated public shelter demand and available capacity by storm scenario. (Shelter locations and capacities provided by each county for the transportation analysis are preliminary figures and are subject to change as shelters are analyzed further by shelter officials.) Shelter space is generally adequate in the study area counties for in-county demand during a hurricane. However, in Palm Beach County for the most intense hurricane

and the largest imaginable public response, shelter space could be overburdened. Complicating the issue is the fact that many late evacuees from south of Palm Beach County could get trapped in Palm Beach County due to lane constrictions on the Florida Turnpike. This would add to public shelter demand. Once capacities are firmly established, they should be compared to the shelter demand figures for identification of shelter deficits.

Traffic Volumes and Critical Roadway Segments

The Transportation Model Support Document provides the assigned evacuating vehicle figures for all roadway segments in each county's evacuation network. In addition, the appendix provides the volume to service volume ratios calculated for each link. Those roadway segments with the highest ratios were identified as the critical links for each county. Table 6-6 lists the critical roadway segments by county. Critical links and intersections are listed in order of severity. These links control the flow of evacuation traffic during a hurricane evacuation and are key areas for traffic control and monitoring.

Estimated Clearance Times

The most important product of the transportation analysis is the clearance times developed by storm scenario and by behavioral characteristics for each county. Clearance time is one of two major considerations involved in issuing an evacuation or storm advisory. Clearance time must be weighed with respect to the arrival of tropical storm winds to make a prudent evacuation decision. Figure 6-14 illustrates these two timing issues of evacuation and their relation.

Clearance time is the time required to clear the roadway of all vehicles evacuating in response to a hurricane situation. Clearance time begins when the first evacuating vehicle enters the road network (as defined by a hurricane evacuation behavioral response curve) and ends when the last evacuating vehicle reaches an assumed point of safety. Clearance time includes the time required by evacuees to secure their homes and prepare to leave (referred to as mobilization time), the time spent by evacuees traveling along the road

COMPONENTS OF EVACUATION TIME

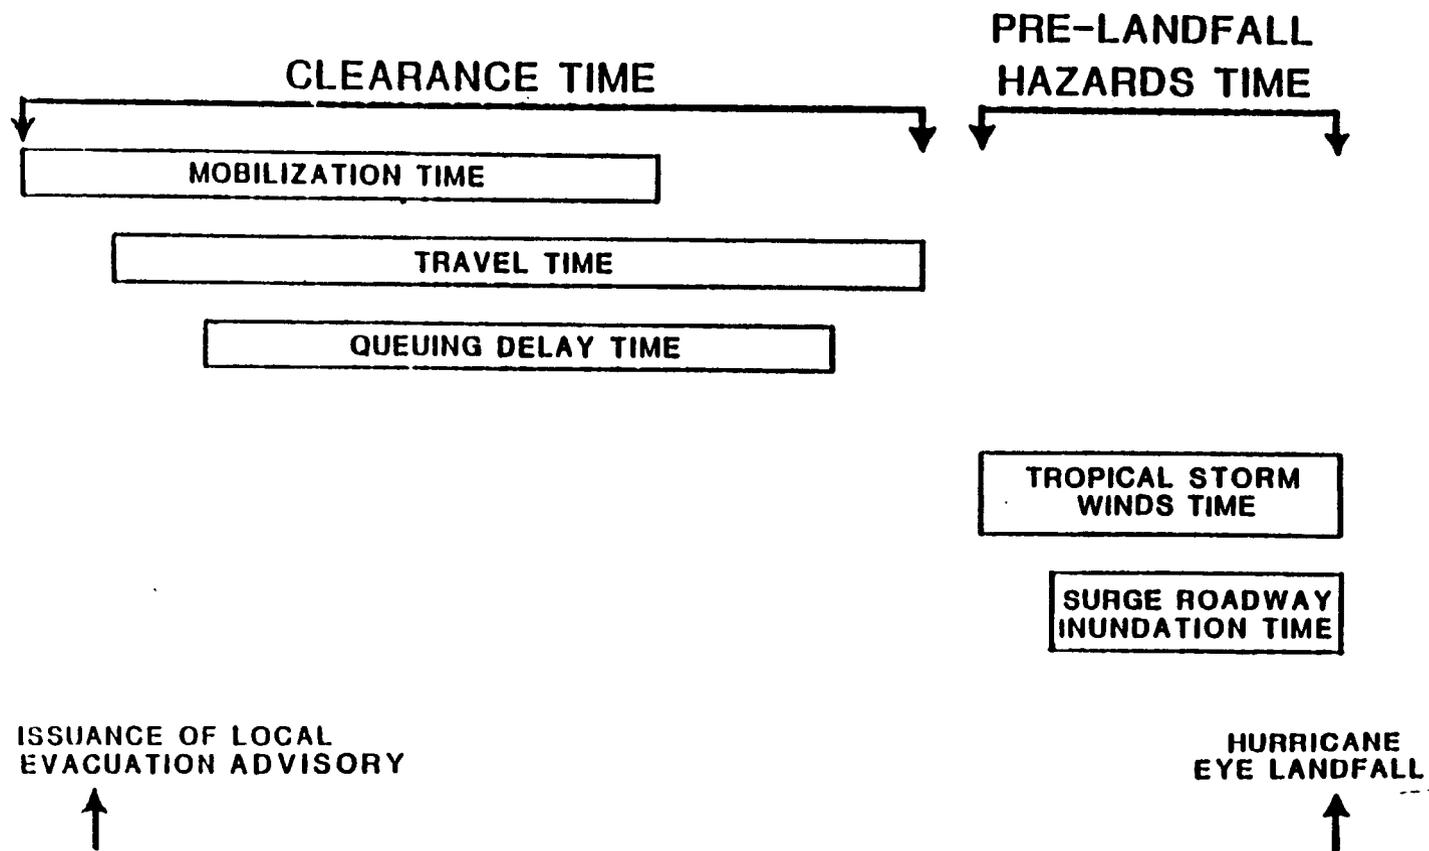

Figure 6-14

network (referred to as travel time), and the time spent by evacuees waiting along the road network due to traffic congestion (referred to as queuing delay time). Clearance time does not relate to the time any one vehicle spends traveling on the road network.

Generally, clearance times allow for the last vehicle leaving to reach the county line. However, for the Treasure Coast region there are many regional and state clearance time issues that require us to look beyond one county or study area's boundaries. Traffic congestion could be severe along the Florida Turnpike and I-95 as both facilities go from three northbound to two northbound lanes within the region. For those southeast Florida and Treasure Coast evacuees who make it through these bottlenecks, a recent Florida Peninsula Hurricane Evacuation Study shows that the I-75/Florida Turnpike interchange at Wildwood could be the most severe bottleneck within the state transportation network.

Table 6-7 presents the clearance times estimated for each county and for the region as a whole. Clearance times are stratified by intensity of hurricane (storm scenario), by rate of response on the part of the evacuating population, and by level of seasonal occupancy. It is important to note that clearance times are based on the assumptions that local officials will be successful in evacuating residents out of dwelling units located in the areas shown as flooded by storm surge (by the SLOSH model). The hazards analysis chapter of the Technical Data Report defines these surge limits and the theory behind their derivation.

TRAFFIC CONTROL ISSUES

The movement of evacuating vehicles during hurricane evacuations requires extensive traffic control efforts to make maximum use of roadway capacity and to expedite safe escape from hurricane hazards. The development of traffic control techniques for critical evacuation roadway links and intersections should always be developed by local police, state highway patrolmen, state DOT, local traffic engineers, emergency management personnel and the U.S. Coast Guard working together cooperatively. The following traffic control issues are recommended for consideration:

1. As manpower supply allows, ideally officers should be stationed at each critical intersection to move traffic, and to assist disabled vehicles. Critical links and intersections discussed previously should be used as a starting point in developing manpower assignments.

Medium Response	47-1/2 hours	54-1/4 hours
Long Response	47-3/4 hours	54-3/4 hours
Extra Long Response	48 hours	55 hours

Note: These times reflect the accumulation of Lower southeast Florida evacuation vehicles along with the out of county vehicles produced by Treasure Coast Counties on both the Florida Turnpike and I-95. Preliminary analyses from the Florida Peninsula Hurricane Evacuation Study show that clearance times could be much higher than these if a major hurricane forces the evacuation of southwest Florida and the bottleneck moves up to the interchange of I-75 and the Florida Turnpike at Wildwood.

2. All available tow trucks should be positioned or on call along key travel corridors and critical links. At a minimum, tow trucks should be at major bridge crossings to remove disabled vehicles.
3. Where intersections will continue to have signalized control, signal patterns providing the most "green time" for the approach leading away from the coast should be actuated by the State Department of Transportation field office or local traffic engineer's office as appropriate.
4. All draw/swing bridges needed for evacuation should be located in the "down" position during a hurricane warning if possible. Boat owners must be made aware of flotilla plans and time requirements for securing vessels. Optimally, recreational vehicles should be moved to safe harbor during or before hurricane watch. This judgement will need to be made on a case by case basis through discussions between the U.S. Coast Guard, local emergency officials and the State DOT.
5. Manual direction of traffic should be supplemented by physical barrier/cones that are adequately weighted down and which are placed to channel traffic and minimize merging conflicts.
6. The movement of mobile homes, campers and boat trailers along evacuation routes should be minimized or even prohibited after a hurricane warning is issued.
7. The collection of tolls should be suspended on facilities such as the Florida Turnpike at some point during an evacuation.
8. Martin County residents who are evacuating dwelling units north of the St. Lucie River to go out of the region should be encouraged to use Pt. St. Lucie Blvd. in St. Lucie County to access the Florida Turnpike and I-95.
9. Any measures to create at least a temporary third northbound lane (using the right hand shoulder) on the Florida Turnpike and I-95 out of the Treasure coast region should be aggressively pursued by state transportation and law enforcement officials.
10. State emergency management officials must aggressively pursue the identification and facilitation of some major regional and state shelter intercept facilities.
11. Roadway closure plans must be developed to end evacuations on the Florida Turnpike, so that evacuees are not stranded on open stretches of highway or in Palm Beach and St. Lucie Counties as the leading hazards begin to arrive.

CHAPTER SEVEN

DECISION ARCS

PURPOSE

This chapter describes the Decision Arc Method, a hurricane evacuation decision-making tool that uses the clearance times determined by the Transportation Analysis in conjunction with National Hurricane Center advisories to calculate when evacuations must begin in order for them to be completed prior to pre-landfall hazards.

BACKGROUND

Along the Atlantic seaboard, hurricanes do not ordinarily approach landfall from a direction perpendicular to the coastline but are often recurving from the tropics and make landfall on a track more nearly parallel to shore. At a typical angle of approach to the shoreline, an error of 10 degrees in predicting the hurricane track can easily mean a 100 nautical mile difference in the point of landfall 24 hours later. Also, as hurricanes move out of the tropics toward the central Atlantic coast, they often lose their steering air currents and begin to behave somewhat erratically. In some cases, hurricanes have become totally unpredictable. Understandably, hurricane forecasting along the Atlantic coast has its uncertainties. The average error of 12 hour forecast landfall positions for Atlantic coast tropical cyclones (including storms of less than hurricane intensity) during 1970-79 was about 50 nautical miles and, for 24 hour forecasts, landfall position error was about 110 nautical miles.

When a hurricane approaches a coastline at an acute angle, which is the usual case along the Atlantic seaboard, an error in forecast landfall position will increase or decrease the distance to landfall, possibly resulting in a significant error in forecast time of landfall. The forward motion of hurricanes can also accelerate and decelerate, causing the time of landfall to be even more unpredictable. Since hurricane evacuation decision making and mobilization have typically been dependent upon forecast landfall position and time of landfall, a method

was needed that would help negate forecast errors by correlating evacuation operations in each county with hurricane position.

It is recommended that hurricane vulnerable jurisdictions investigate the various hurricane evacuation decision-making computer programs in use today. These programs incorporate Hurricane Evacuation Study data, including some version of the decision arc method presented in this chapter; they can be very useful in speeding needed calculations and automatically using checklists of factors that should be considered in deciding both if and when to evacuate. Even if a computer program(s) is used, familiarity with the concepts presented in this Chapter is of utmost importance. This will enhance confidence in the use of the software and will also ensure the ability to function in the event of power outages or computer failure.

DECISION ARC COMPONENTS

A. General.

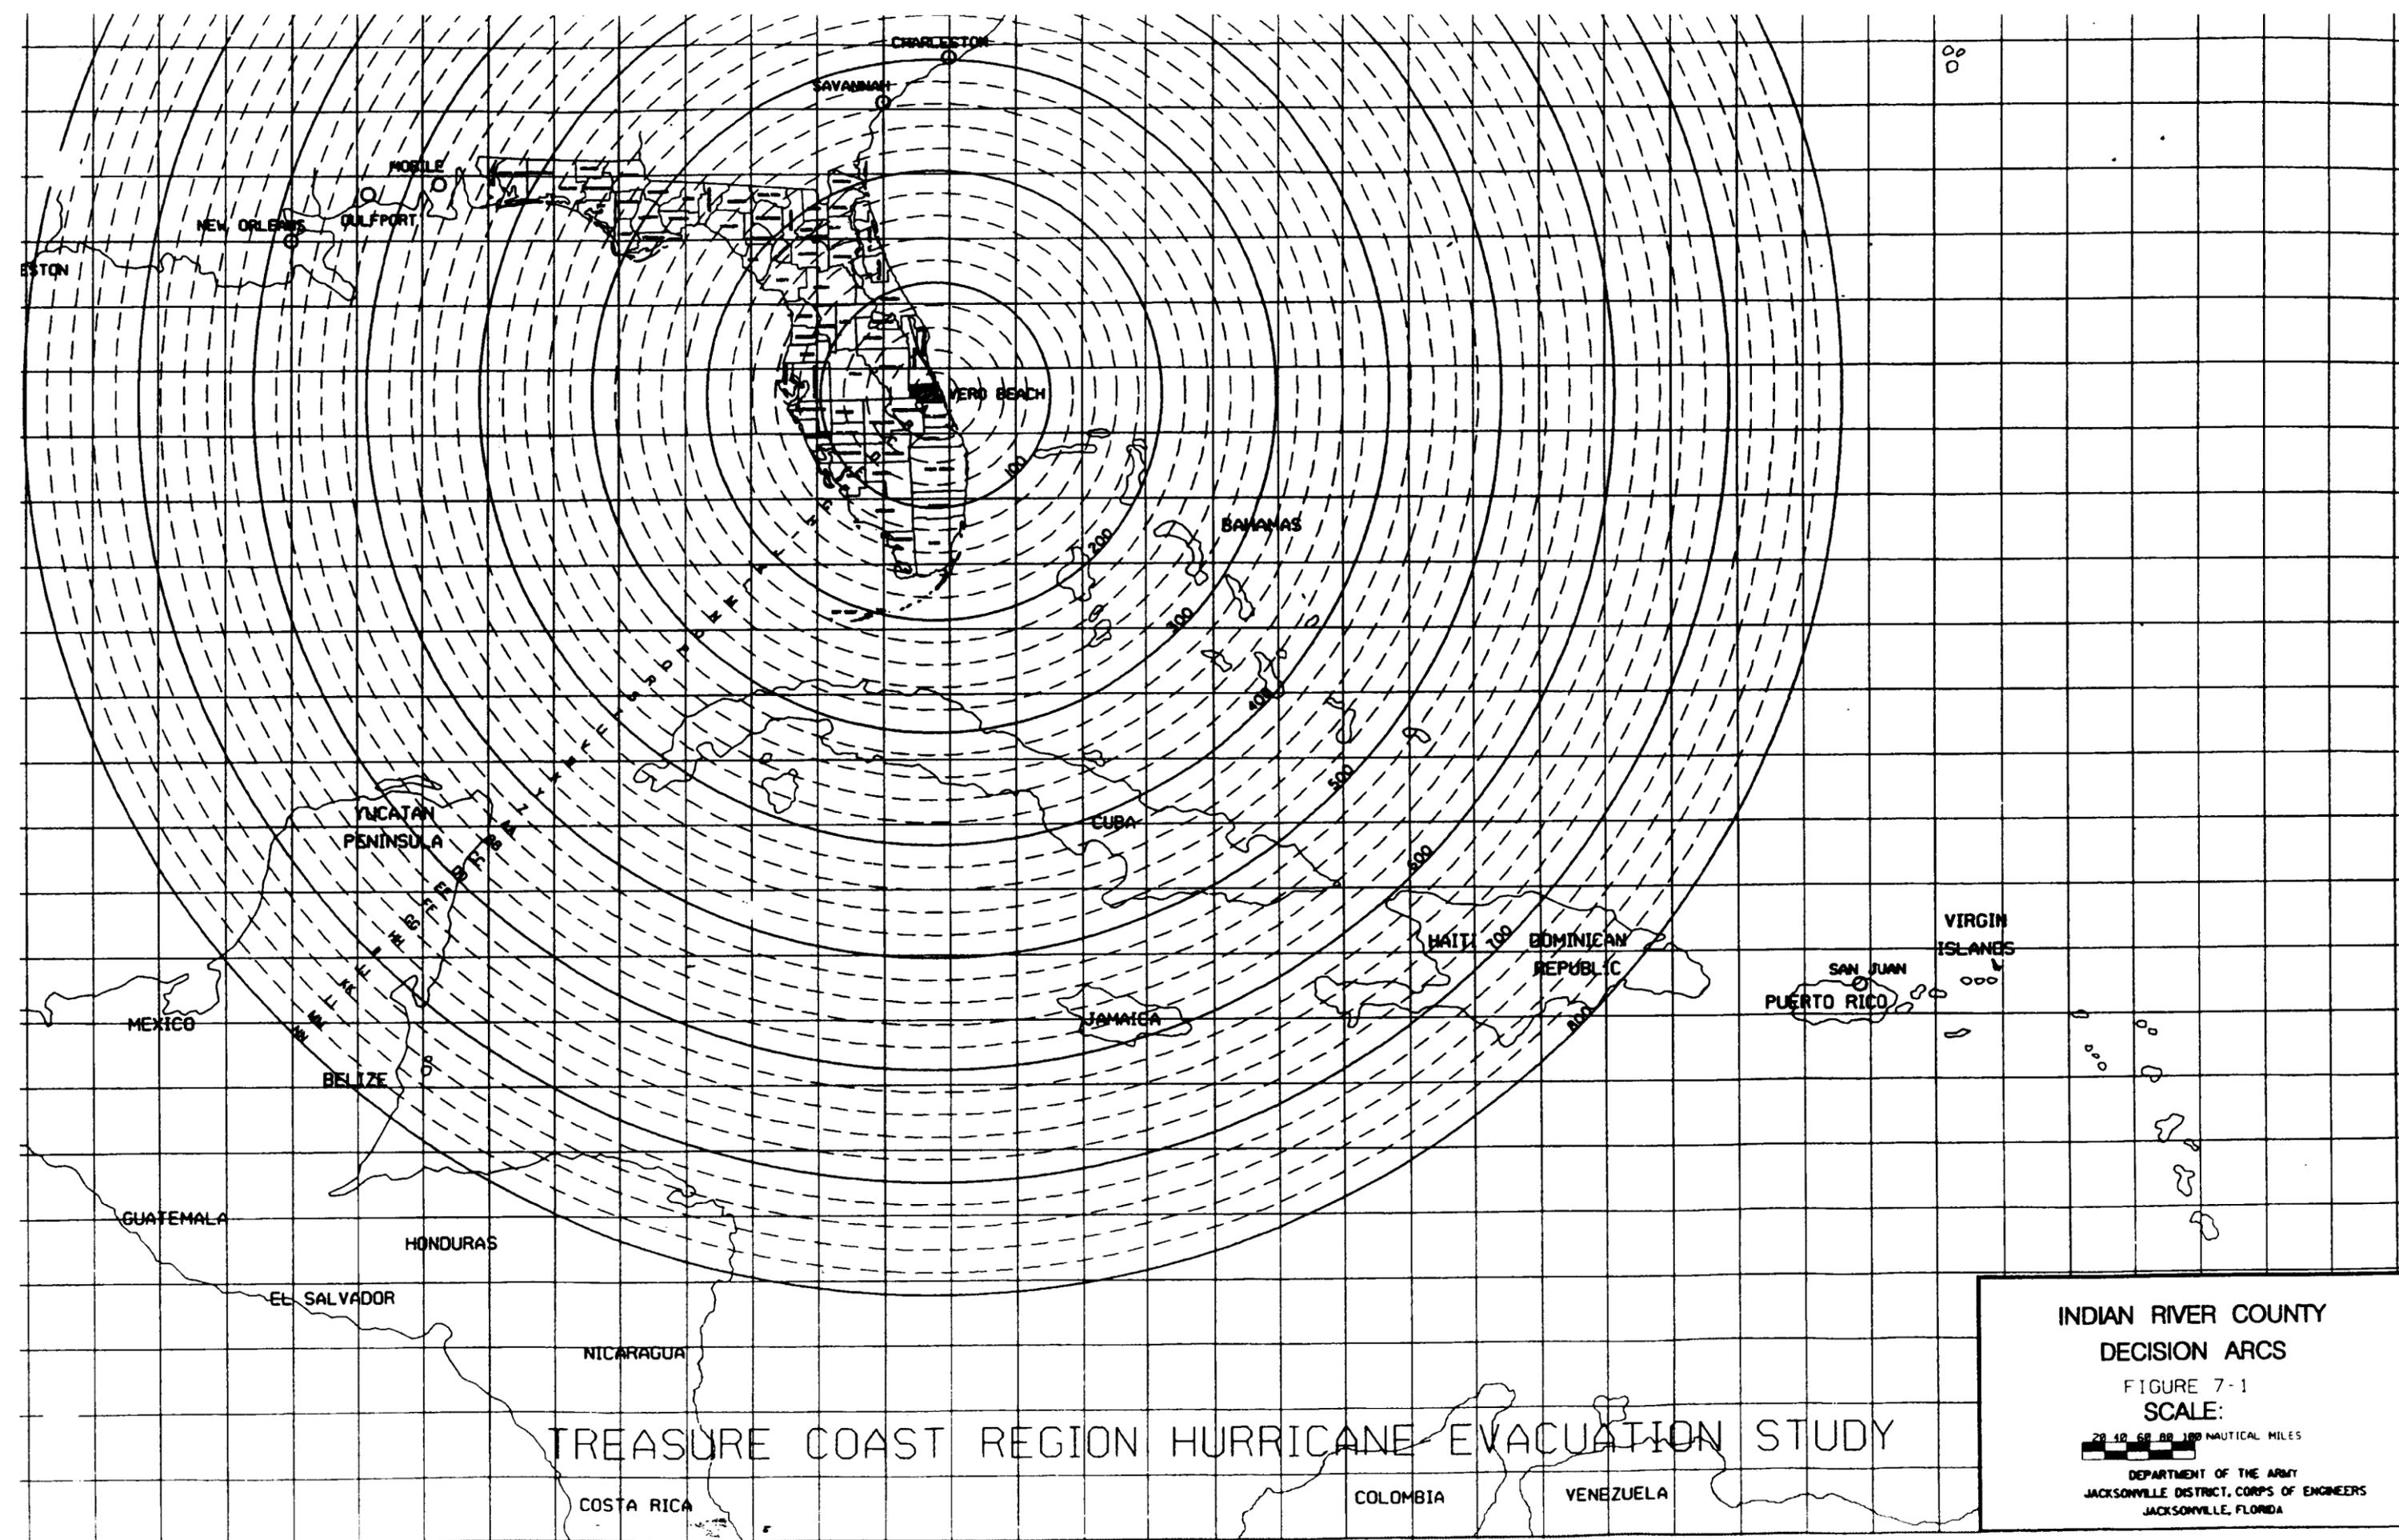

The Decision Arc Method employs two separate but related components which, when used together, depict the hurricane situation as it relates to each county. A specialized hurricane tracking chart, the Decision Arc Map, is teamed with a transparent two-dimensional hurricane graphic, the STORM, to describe the approaching hurricane and its location in relation to the county considering evacuation.

B. Decision Arc Map.

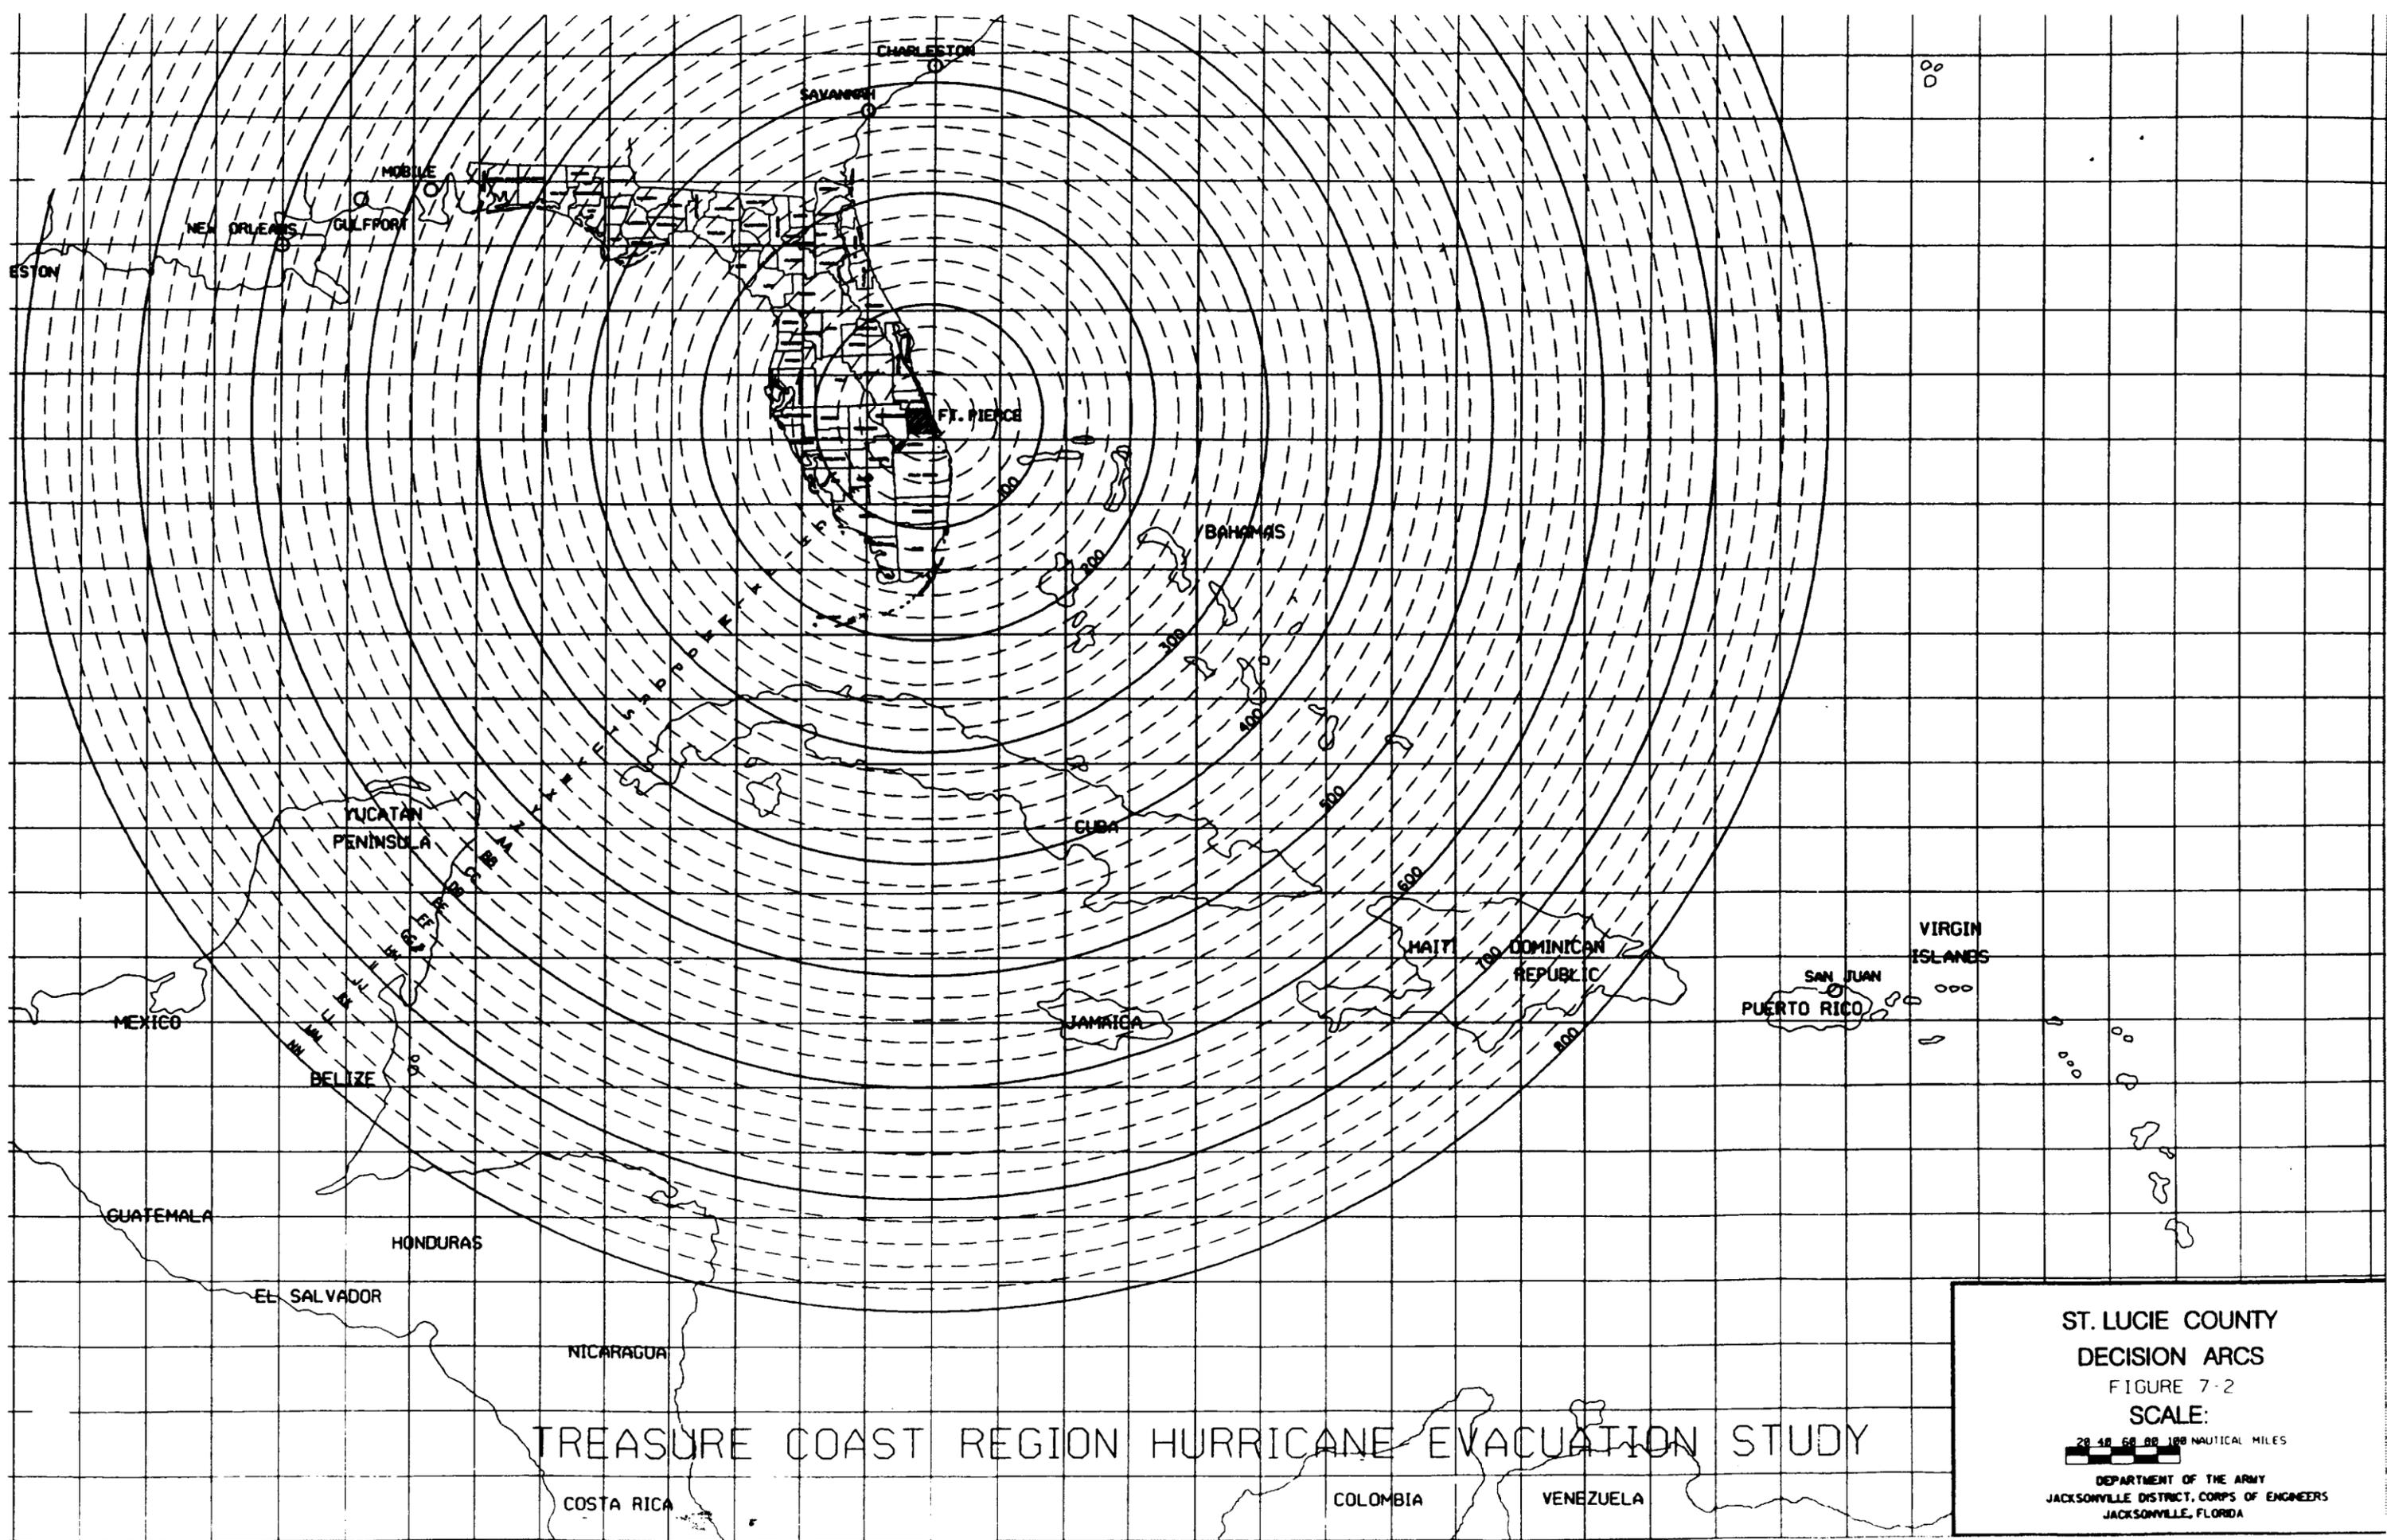

In order to properly evaluate the last reported position and forecast track of an approaching hurricane, special hurricane tracking charts have been developed. Superimposed on an ordinary tracking chart is a series of concentric arcs centered on the most populous coastal area in each county and spaced at 20-nautical miles intervals. These arcs are labeled in nautical miles measured from their center and also, for convenience, alphabetically. Figures 7-1 through 7-4 (located in Appendix D) show the Decision Arc Maps for each county in the Treasure Coast Region.

C. STORM.

The Special Tool for Omni-directional Radial Measurements (STORM) is used as a two-dimensional depiction of an approaching hurricane. It is a transparent disk with concentric circles spaced at 25 nautical mile intervals, their center representing the hurricane eye. These circles form a scale used to note the radius of 34 knot winds (gale force) reported by the National Hurricane Center in the Marine Advisory and Public Advisory.

B. Storm Surge Model

Storm surge is the response by the ocean to meteorological forces. The model's governing equations are those given by Jelesnianski (1967), except now for the inclusion of the finite amplitude effect. Coefficients for surface drag, eddy viscosity and bottom slip are the same as those used in an earlier model (Jelesnianski, 1972). There is no calibration or tuning to force agreement between observed and computed surges; coefficients are fixed, and do not vary from one geographical region to another.

Special techniques are incorporated to model two-dimensional inland inundation, routing of surges inland when barriers are overtopped, the effect of trees, the movement of the surge up rivers, and flow through channels, cuts and over submerged sills. Besides surge, other processes affect water height (section 4B), but are not incorporated in the model.

Not surprisingly, the accuracy of modeled surge values increases as the accuracy of the input terrain and storm data improves.

4. OUTPUT AND INTERPRETATION OF THE MODEL RESULTS

A. Output from the SLOSH Model

The output for the Palm Beach "SLOSH" model consists of maps of water heights. At each grid point, the water height is the maximum value that was computed at that point during the 72 (maximum) hours of model time. Thus, the map displays the highest water levels and does not display events at any particular instant in time. The analyzed envelopes of high water show shaded areas that represent dry land which has been inundated and contours of high water relative to mean sea level (MSL). Height of water above terrain was not calculated because terrain height varies within a grid square. For example, the altitude of a 1-mile grid square may be assigned a value of 6-ft MSL, but this value represents an average of land heights that may include values ranging from 3 ft to 9 ft MSL. Thus, a surge value of 8 ft in this square,

implying 2 ft average depth of water over the grid's terrain, would include some terrain without inundation and other parts with as much as 5 ft of overlying water. Therefore, the depth of surge flooding above terrain at a specific site in the grid square is deduced by subtracting the actual terrain height from the model-generated storm surge height in that square. Also supplied are printout lists of values of surge height, wind speed and wind direction for each of 110 sites. The values of wind speed and direction are ten-minute averages, every 30 minutes. These are useful for determining the time of onset of gale force winds and surge heights, for evacuation planning.

B. Interpretation of Results

Even if the model is supplied accurate data on storm positions, intensities and sizes, the computed surges may contain errors of +/- 20% of observed water levels. These primarily stem from:

- 1) Maps that are outdated: The maps which supplied heights of terrain and depths of water sometimes did not include changes, often man-made, that had altered the heights and positions of barriers (e.g., highway and railway embankments) and depths and locations of channels. Inaccuracies of topography or bathymetry will contribute directly to errors in the modeling of all storm surges.
- 2) Anomalous water heights: Sea level can be at an altitude different from "mean sea level," days or even weeks before a storm is actually affecting a basin. The value of the actual, local sea level -- the "local datums" for pre-storm anomaly in the Atlantic Ocean -- must be supplied to the model, before calculations are initiated.
- 3) Local processes, such as waves, astronomical tides, rainfall and flooding from overflowing rivers: These processes are usually included in "observations" of storm surge height, but are not surge and are not calculated by the SLOSH model.

grid, which would have radial increment (ΔR) that was invariant with radius, this grid uses a ΔR that increases with increasing distance from the grid's pole. The result is that in each grid of the mesh, the increment of arc length (ΔS) of the side of a grid "square" is approximately equal to the radial increment of the "square," or $\Delta S \approx \Delta R$.

The telescoping grid is a compromise between conflicting needs. What is desired is that the model domain include a large geographical area, but also that small, detailed topography be included in the model. In a Cartesian coordinate system, this combination of big area, but spatially-small grid increment, requires that a computational mesh with many grid squares be used. A large mesh requires a computer with a large central processing unit as well as more time to perform calculations in the more numerous grid squares. The telescoping grid, by comparison, permits a resolution of these conflicting needs: over land, which is the area of greatest interest, it has an acceptably small spatial resolution. Thus, each grid square closest to the pole (at $I = 1$) represents an area of about 0.59 square miles. This permits inclusion in the model of topographic details such as highway and railroad embankments, causeways, levees, and dikes in harbors. But, with increasing distance from the pole, the range increment and arc lengths which border each grid "square" become progressively larger: at maximum distance from the pole ($I = 71$) each grid square contains about 2.62 square miles. As a result, a large geographic area is included in the model, so that the effects of the model's boundaries on the dynamics of the storm are diminished and the storm's physics are better emulated.

The telescoping grid has some disadvantages. Primarily, these stem from the distortion that occurs when the basin is remapped onto a display that has constant-sized increments in the vertical and horizontal, as happens when the basin is printed out by a conventional (computer)line printer. This distortion from remapping produces some difficulties in "reading" the results

by the uninitiated. For example, neither latitude nor longitude lines remain uncurved and "parallels" become non-parallel, although the projection is conformal. To surmount these disadvantages, the storm surge results have been reanalyzed onto a conventional map projection. They are presented in the Appendix.

The grid is tangent to the earth at the basin center, Palm Beach, Florida at $26^{\circ}42'30''\text{N}$ and $80^{\circ}02'\text{W}$. There, the grid increment is 0.85 statute mile. The pole (or origin) of the grid is located at $26^{\circ}41'30''\text{N}$ and $81^{\circ}18'\text{W}$.

3. SLOSH MODEL

A. Hurricane Model and Input

The hurricane model which drives the storm surge model was developed by Jelesnianski and Taylor (1973). It is a trajectory model of a stationary vortex and it balances the forces from pressure gradient, centrifugal, Coriolis and surface frictional effects. Adjustments are made to the computed vector wind to incorporate the hurricane's forward motion. The model's input includes the radius of maximum wind (RMW) and the difference (ΔP) in sea-level pressure between the ambient value and the minimum value in the storm's center. Directly measured wind vectors are not used. The model also requires input of the coordinates of the storm's center. Thus, input data include thirteen sets of latitude, longitude, ΔP and RMW, at six hour increments, beginning 48 hours before storm landfall and ending 24 hours after landfall. These 13 sets are then linearly interpolated into values/positions at hourly (or smaller) time increments. The model then generates the meteorological forces--surface stress and the gradient of atmospheric pressure--that drive the underlying ocean.

Factors such as the foregoing must be considered when comparisons are made between modeled and observed values of storm surge.

5. HURRICANE CLIMATOLOGY

A. Tracks

Between 1886 and 1990, 48 tropical cyclones of hurricane intensity passed within 125 statute miles of Palm Beach, Florida (Neumann et al., 1987), for an average of one hurricane within the 125-mile circle every 2.2 years (see Table 2).

Figures 2-9 show the tracks of these 48 storms with hurricane force winds. Tracks of storms heading west or west-southwest are in Figure 2; heading west-northwest are in Figure 3; heading northwest are in Figure 4; heading north-northwest are in Figure 5; heading north are in Figure 6; heading north-northeast are in Figure 7; heading northeast are in Figure 8; and heading east-northeast are in Figure 9. In Figures 2-9, the tracks are labelled at 6-hour intervals, with month/day/hour (GMT).

The tracks represent "best estimates" and are based on a variety of data sources. Historically, storm location, motion and strength were only inferred, from analyses of wind, pressure and cloud observations made at ships and land stations being influenced by the storm. In 1943, aircraft reconnaissance of hurricanes began. Not until 1959 were there land-based weather radars, as now at Miami, Daytona Beach, and Tampa, which could be used to observe and record structure, development and motion of precipitation fields, and help infer center location and radius of maximum winds. The 1960's saw the advent of photography of tropical storms from weather satellites. Observations by aircraft, radar and satellite have shown that the tracks of centers of hurricanes contain wobbles, gyrations and cycloidal motions (Lawrence and Mayfield, 1977) and that there often are rapid changes in size and intensity of rain bands, contractions of eyewall diameter and formation of concentric

Notes:

- (1) Storm number for this list.
- (2) Year, month and date that storm had maximum winds exceeding 74 mph and was closest to Palm Beach, Florida.
- (3) Storms were not formally named before 1950.
- (4)-(5) Distance (statute miles) and direction (degrees) from Palm Beach to storm when it passed abeam.
- (6) Maximum sustained wind speed near storm center while center was within 125 statute miles of Palm Beach. This is not necessarily the wind recorded at a given site.
- (7)-(8) Storm heading and forward speed (mph) at hour of closest point of approach.

("double") eyewalls. These factors, poorly documented even today, indicate asymmetries in the storm's dynamical structure and can affect the storm's surge. But they usually are smoothed out of analyses, as in Figures 2-9.

B. Intensities

Hurricane intensity is usually defined by measurements at sea level of the maximum sustained wind speed and/or by minimum barometric pressure. Neither of these is easily obtained. Accurate estimates of these parameters at sea level were acquired only when a ship or land station was traversed by the storm's "eye." Minimum central pressure was gotten only when a barometer was in the precise path of the storm's center. Because the area covered by the strongest winds is much larger than that covered by the pressure minimum, strength of many older storms was deduced from measurements of wind speed. However, with the advent of aircraft reconnaissance, measurements made at flight level of meteorological parameters allow the calculation of barometric pressure at sea level. By comparison, winds at sea level are not so readily deduced from flight level data. For all the storm tracks in Figures 2-9, an estimate was made of the maximum wind speed at intervals of 6 hours. For some, only very indirect evidence exists of actual speeds. From the hourly values of the maximum wind speed inside the 125 mile circle, the largest value was selected. This maximum sustained wind speed for the hurricane is listed in Table 2 under the heading of "wind (in circle)." Storm heading and forward speed at hour of closest point of approach are listed in the last two columns.

The values listed in column 6 sometimes are poor estimates of the maximum wind speed; the following must be considered:

- 1) Actual wind speeds and directions exhibit gustiness.
- 2) The "average wind speed" has been calculated with a variety of time intervals over the years; thus, one can find historical wind records that

have used time periods such as 1 hour, or 10 or 5 minutes or 1 minute as the "standard" period of measurement. Given the same record from a recording anemometer, the use of each of these measurement periods would likely yield a different average wind speed, with shorter periods probably giving higher average speeds.

- 3) The platforms for measuring maximum surface wind speed have changed over the years; data from ship and land stations now are supplemented by remotely-sensed data from aircraft, satellites and radar. However, the remote platforms, especially the last two, observe the motions of clouds or precipitation echoes, and these motions are not wind speed, nor are they at sea level.

Because of these limitations in determination of maximum wind speed, the SLOSH model uses storm-center sea-level pressure as a measure of storm intensity in modeling the Palm Beach basin.

6. MAPS OF MAXIMUM ENVELOPE OF WATER ("MEOW") FROM SLOSH RUNS USING DATA FOR HYPOTHETICAL HURRICANES

A. Hypothetical Storm Tracks and Populations

The skill of the SLOSH model was evaluated by Jarvinen and Lawrence (1985), who compared modeled and observed surges at 523 sites during 10 hurricanes. They found that the mean absolute error in surge height calculated by SLOSH was 1.4 ft. Although the error range was from -7.1 ft to +8.8 ft, the standard deviation was only 2.0 ft and 79% of the errors lay within one standard deviation of the mean error, -0.3 ft. (On the average, modeled values were slightly less than those observed.)

Because of this skill in calculating storm surge, the SLOSH model was used to create maps of surge flooding in the Palm Beach basin for use in evacuation planning. The model was supplied with data from hypothetical storms and the

resulting surge calculations were composited to produce maps of the maximum envelope of water. This section describes why these calculations were made and how the compositing was done.

Storm surge height partly depends on distance between the location of a particular site and the storm's center. For a single storm, the model would produce a map of surge height for the modeled period of time (usually 72 hours), with values valid for only that particular storm track. If there were two storms, identical in every respect except that one followed a track parallel to, but separated from the other by 50 miles,¹ and if the model was run with first one and then the other set of storm parameters, and a comparison made of surge values, then very likely there would be geographical sites having surge values from one storm differing markedly from those modeled for the other storm. This dependency of surge height on storm track can be troublesome, when preparing plans for emergency evacuation. Maps are needed for basin-wide surge flooding potential--maps showing surge height for only one intensity (using the categories defined by Saffir and Simpson), one storm speed and direction. We created such maps for this basin by making surge calculations for each of an ensemble of 8 to 13 storms; in an ensemble, all storms had the same intensity and speed and had parallel headings, separated by 15 miles or less. Then at each grid square, the maximum surge value that was calculated from any storm in the ensemble was extracted and saved. After this procedure was performed for all grid squares, the result was a basin map

¹A difference ("error") of 50 miles in storm track is not very large when compared to the vagaries of tracks of real hurricanes. The average error of 12-hour forecast landfall position, for U.S. Atlantic coast tropical cyclones, during 1970-1979, was about 59 statute miles, while for 24-hour forecasts, landfall position error was about 125 statute miles (Neumann and Pelissier, 1981). Thus, if a storm were forecast to make (eye) landfall at Palm Beach, Florida, in 24 hours, and if, in fact, it made landfall anywhere between Islamorada and Cape Canaveral, the error in forecast landfall position would be no worse than average.

depicting the "maximum envelope of water," or MEOW, for the specified storm category, direction and speed. For the Palm Beach basin, the hypothetical storms were specified to move in one of ten directions, at one constant speed, as summarized in Table 3. There were 13 tracks for the west-southwestward (WSW) moving storms (Figure 10), 13 tracks for the westbound (W) storms (Figure 11), 12 tracks for the west-northwestward (WNW) moving storms (Figure 12), 9 tracks for the northwestbound (NW) storms (Figure 13), 8 tracks for the north-northwestward (NNW) moving storms (Figure 14), 8 tracks for the northward (N) moving storms (Figure 15), 9 tracks for the north-northeastward (NNE) moving storms (Figure 16), 11 tracks for the northeastward storm headings (Figure 17), 13 tracks for the storms moving east-northeastward (ENE; Figure 18), and 13 tracks for the eastbound (E) storms (Figure 19). In total, 545 hypothetical storms were run with the SLOSH model to create the results to be presented below. The selection of intensities, directions and speeds was based on advice of hurricane specialists at NOAA's National Hurricane Center.

B. Intensities and Radii of Maximum Winds of Hypothetical Storms

Most hurricanes weaken after making landfall because the central pressure increases (the storm "fills") and the RMW tends to increase. But as seen in Figures 10-19, some tracks of hypothetical storms do not intersect the coast of mainland Florida. On some of these tracks the label "INV" is shown, which indicates that the ΔP and RMW used to model storms on this track were invariant for all 72 hours of model time. All other storms underwent pressure filling and RMW increases with time, as summarized in Table 4. These rates of change were based partly on the work of Schwerdt et al. (1979).

C. Initial Water Height

Based on observations from tide gages in the area of this basin, tidal anomalies of about +1 ft MSL before arrival of a hurricane are not uncommon.

Table 3. Palm Beach basin's hypothetical storms: Directions, speeds, (Saffir/Simpson) intensities, number of tracks and the number of runs.

Direction	Speed (mph)	Intensities	Tracks	Runs
WSW	12	1 through 5	13	65
W	12	1 through 5	13	65
WNW	12	1 through 5	12	60
NW	12	1 through 5	9	45
NNW	15	1 through 5	8	40
N	15	1 through 5	8	40
NNE	15	1 through 5	9	45
NE	15	1 through 5	11	55
ENE	15	1 through 5	13	65
E	12	1 through 5	13	65

Total = 545

Table 4. Time change of pressure difference and radius of maximum wind for hypothetical hurricanes not labelled "invariant" in Palm Beach basin.

A) Values of pressure difference (ΔP , millibars) and radius of maximum wind (RMW, statute miles), beginning at time of landfall (LF) of center of storm and 6, 12, 18 and 24 hours after LF.

Category	Landfall		LF + 6		LF + 12		LF + 18		LF + 24	
	ΔP	RMW								
1	20	20	12	25	10	30	10	35	10	40
2	40	20	30	25	20	30	10	35	10	40
3	60	20	48	25	39	25	29	30	18	35
4	80	20	60	20	48	25	38	30	29	35
5	100	20	63	20	50	25	40	30	30	35

B) Values of pressure difference (ΔP , millibars) at landfall (LF) and at each of the first six hours after LF.

Category	Landfall	LF+1	LF+2	LF+3	LF+4	LF+5	LF+6
	ΔP						
1	20	18	16	15	14	13	12
2	40	38	37	35	34	32	30
3	60	58	56	54	52	50	48
4	80	73	68	65	63	61	60
5	100	80	74	70	67	65	63

Furthermore, to simulate conditions at time of high tide, an additional 1.5 ft of water was included for oceanic values. Inland lakes and bays, found to have a smaller tidal response, had only 1.0 ft of water added. Thus, initial ocean datums of 2.5 ft were used, while for inland lakes and bays, initial datums of 2.0 ft were used. Therefore, the resulting calculations of storm surge, using these initial datums, represent conditions at time of high tide.

D. The "MEOW" Figures

There are 50 MEOWS, which are presented in the Appendix. They are displayed using a conventional map projection. The east-central coast of Florida (Figure 20) is subdivided into three overlapping regions (Figure 21), to optimize the legibility of the MEOW results. The MEOW figures are grouped by direction: west-southwestbound storms' MEOWS are in Figures A1-A5, westbound storms' MEOWS are in Figures A6-A10, west-northwestbound storms' MEOWS are in Figures A11-A15, northwestbound storms' MEOWS are in Figures A16-A20, north-northwestbound storms' MEOWS are in Figures A21-A25, MEOWS for northbound storms are in Figures A26-A30, Figures A31-A35 depict MEOWS for north-northeastbound storms, northeast-moving storms' MEOWS are in Figures A36-A40, MEOWS for east-northeast moving storms are in Figures A41-A45, and Figures A46-A50 display MEOWS for eastbound storms. In the figures, the contours represent the height of water above mean sea level, in 1-ft increments, while the shaded areas indicate land areas that were modeled to have been inundated.

Evacuees Leaving the Local Area	19

**Background and Approach:
Behavioral Science and
Hurricane Evacuation Planning**

Evacuation outcomes depend upon many factors, including how the public responds to the event, and in hurricane evacuation planning, one must make assumptions about those factors. If one makes unreasonable assumptions, an actual evacuation is unlikely to proceed as anticipated. The public responses having the greatest impact upon an evacuation are

1. The number of people who evacuate.
2. The number of vehicles used in the evacuation.
3. How promptly evacuees leave.
4. The number of evacuees who leave or attempt to leave the local area and where they go.
5. The number of evacuees who seek refuge in public shelters.

Deriving Correct Assumptions

Regardless of how detailed, formal, or quantitative an evacuation plan appears, it contains assumptions about behaviors such as those discussed above. Even if the assumptions are not deliberately and explicitly addressed, there are implicit or implied values for them. For example, planners who say they make no assumptions at all regarding whether people outside the recommended evacuation zone will evacuate are in fact assuming that none of those people will leave. Any time an evacuation plan is "tested" to ascertain the length of time required to

complete an evacuation under the plan, the test includes quantitative assumptions regarding behavioral factors. The issue is not whether such assumptions should be made, because they must; the issue is what the assumptions should be.

There are at least three basic ways to derive behavioral assumptions:

1. Conduct interviews with people in a large number of locations asking what they did in multiple hurricane threats, documenting patterns of behavior under various conditions (general response model).
2. Conduct interviews asking people what they did in one particular evacuation (single event survey).
3. Conduct interviews asking people what they would do during a hurricane threat (hypothetical survey).

An Integrated Approach

Building a Quantitative General Response Model. A response model can be constructed to indicate quantitative values of specific responses, given a particular set of circumstances which the planner specifies. The extent of shadow evacuation in hurricanes, for example, can be forecast by specifying the severity of the storm, hazardousness of the neighborhood, and actions taken by public officials.

This is the heart of HMG's approach to formulating behavioral assumptions for hurricane evacuation planning. We are fortunate to have amassed actual response data from many hurricane evacuations spanning a wide geographical area and a variety of hurricane threat circumstances over a period of roughly three decades.

HMG's general response model has been used successfully in evacuation plans along the Gulf and Atlantic coasts, including the Treasure Coast region in 1988, and it currently is being enhanced by surveys conducted concerning public response in Andrew in south Florida and Louisiana. Thus, for each of the

behaviors to be anticipated, the model predicts a quantitative value, depending upon specific situations and circumstances specified.

A common concern expressed about the general response model is that it is based upon responses of people in "other places" and that "our people are different." Actually the strength of the general model is that it accounts for differences in responses as they vary because of demographic characteristics of the population, actions by emergency management personnel, physical hazardousness of the study area, and so forth. Evidence of the model's validity lies in its history of accurately explaining and forecasting actual response behavior observed in a variety of places.

Single Event Actual Response Data. It is tempting to overgeneralize from a single evacuation in a particular location. Even the same people will respond differently in different sets of circumstances. Single event data can be very useful if not overused, however. If an evacuation occurs late at night, for example, and the evacuation is urgent, those circumstances tend to lead to fewer people leaving the local area than other circumstances. Thus, if the single event was a late night, urgent evacuation, it might provide an indication of the "worst case" to expect in that location for certain types of behaviors.

Single events also provide opportunities to validate the use of the general response model for forecasting in a specific location. Actual behavior in a single event can be documented and compared to that which would have been predicted by the general response model. Its "fit" gives a clue to how much the model would have to be adjusted to work for the specific location and hazard.

A survey was conducted in 1982 to document how Treasure Coast residents responded during hurricane David in 1979 (Treasure Coast Regional Planning Council, 1983). Data from that survey will be cited and compared to responses normally observed in similar circumstances, as predicted by the general response

model. No actual response data for hurricane Andrew is available for the Treasure Coast region at this time, but it would be useful in further guiding the general response model's application to the region.

Hypothetical Responses. Although hypothetical response data can hardly ever be used literally for quantitative forecasts, HMG has collected much data of this nature, and it does have limited utility when used carefully. It can also be very misleading, however. There are certain consistent biases in hypothetical response data, for example. People are more likely to say they would evacuate in "low risk" situations than they usually do, more likely to say they would leave early than they usually do, and more likely to say they would use public shelters than they usually do. Hypothetical response data can be adjusted to account for those sorts of known biases. Hypothetical data in one location can be compared with that collected elsewhere for an indication of relative variation between the samples. If more people in one location say they would refuse to leave than in another, they probably really are more likely to refuse. At least more effort will be required to have them move. So, although the magnitude of people saying they wouldn't leave might not be quantitatively valid, it at least gives a relative indication. This can be particularly useful when actual response data is also available in the second location.

The 1982 survey also asked Treasure Coast residents what they would do in future hurricanes. Those hypothetical responses will be compared to what people actually did in David, to other hypothetical surveys, and to responses indicated by the general response model.

Evacuation Rates

Response in David

The 1979 survey assigned respondents to one of three evacuation zones: coastal, middle, and interior. The coastal zone is clearly at the highest risk of the three, consisting exclusively of barrier islands. The coastal extent of the interior zone is near the Sunshine State Parkway in St. Lucie and Martin counties as far north as SR 68, then coincides roughly with I-95 north of SR 68. It can be reasonably characterized as relatively low risk, with wind and localized flooding posing the principal hazards. The middle zone, however, is extremely mixed with respect to hazardousness. It includes the mainland coastline bordering the Indian River but extends inland far beyond the probable surge inundation areas.

Evacuation rates documented in David are summarized in Table 1. Clearly, the greatest evacuation rate was in the coastal zone (77%).¹ In the middle zone the rate was somewhat higher in Indian River and Martin than in St. Lucie. This might have been attributable to the slightly higher incidence of mobile homes in Indian River and Martin, differences in actions taken by local officials, and local variations in hazard. People over 65 years old were more likely to evacuate than younger residents, but this too could be confounded with the presence of mobile homes. The elderly were at least three times more likely to live in mobile homes than other age groups.

¹All samples are subject to error, as they are subsets of the entire population from which they were taken. Larger samples are less likely to yield values which differ greatly from the true population value than smaller samples. Table 1 includes an indication of the "error factor" in the 1982 survey following David. The entry ".77 +/- .08", for example, means that 77% of the coastal sample said they evacuated, and one can be reasonably certain that figure is within 8 percentage points of the "true" evacuation rate for the all coastal zone residents.

		IR .23 +/- .06	
		M .27 +/- .05	
		SL .18 +/- .04	

Table 1. Treasure Coast evacuation rates in David.

Patterns of response were very consistent with those documented elsewhere and predicted by the general response model. The 77% evacuation rate in the coastal zone appears lower than one would expect if officials were entirely successful in communicating an evacuation order, but no data was collected indicating whether respondents understood that they were supposed to evacuate. The statistical reliability of the figure is also low due to the relatively few interviews conducted in the coastal zone.

Hypothetical Responses

The hypothetical question attempting to identify people who wouldn't leave is rather meaningless. Respondents were asked how soon they could be ready to leave if government authorities strongly advised them to evacuate. Only 6% said "never", implying from the data that 94% would leave. A majority of these people are at risk only to wind and live in structures more substantial than mobile homes. It is difficult to conceive of a scenario in which they would all be strongly advised

to evacuate because of a hurricane, but if they were, far less than 94% would actually leave from middle and interior areas.

Recommendations

Table 2 summarizes the evacuation rates which should be used for planning. Recommendations are stratified on three dimensions: risk area, strength of storm, and type of housing.

Severe Storm Evacuation Ordered in High and Moderate Risk Areas and Mobile Homes			Weak Storm Evacuation Ordered in High Risk Areas Only but All Mobile Homes		
RISK AREA					
<u>High</u>	<u>Mod</u>	<u>Low</u>	<u>High</u>	<u>Mod</u>	<u>Low</u>
Housing Other Than Mobile Homes					
90%+	75%	30%	85%	40%	20%
Mobile Homes					
95%	90%	80%	90%	75%	65%

Table 2. Evacuation rates to be used for planning.

Risk Area

The risk area categories do not generally correspond to the coastal, middle, and interior areas used in the 1982 survey. High risk areas refer to barrier islands and open coast, which are, however, roughly the same as the 1982 survey's coastal zone. Moderate risk areas refer to areas that would flood in most hurricanes but are not on the open coast. Flood depths and wave action would be less severe than in high risk areas. These would include the most hazardous parts of the 1982 middle area. Low risk areas are normally subject only to hurricane winds. They include parts of the 1982 middle zone and almost all of the interior zone.

Obviously evacuation rates will be higher in more hazardous risk areas. Evacuation rates in the high risk areas, if during a hurricane threat officials are successful in communicating to residents that they need to evacuate, will normally be higher than that observed in David. It is equally important to note that there will also be evacuation from low risk areas, even if residents are not advised to leave. The phenomenon is sometimes called "shadow" evacuation.

Storm Severity

Stronger storms will result in greater evacuation rates because people realize that there is more to fear from stronger storms and because public officials take different actions in stronger storms (communicating evacuation notices more aggressively and to larger areas). Table 2 addresses two scenarios: 1) a severe hurricane in which officials order evacuation from high and moderate risk areas and from mobile homes in low risk areas and 2) a weaker storm in which only mobile home and high risk residents are told to leave. In the latter instance the evacuation shadow in moderate and low risk areas is significantly less.

Mobile Homes

The general response model does not address mobile homes with the same degree of confidence that it addresses more predominant housing because there are not usually enough mobile homes included in post-hurricane surveys to yield reliable conclusions about their occupants. In the 1982 Treasure Coast Survey there were enough mobile homes included, but the analysis didn't separate mobile homes from other housing with respect to evacuation response.

Nevertheless it is clear that mobile home residents are more likely to evacuate than occupants of other housing, all other factors being the same. In both of the scenarios analyzed here it is assumed that public officials advise or order mobile home residents to go to safer structures and communicate that notice to them effectively. To be certain that the notices are communicated effectively,

police should go into mobile home developments to announce the order rather than relying upon media dissemination.

Effect of Andrew

The destructiveness of hurricane Andrew in south Dade county has led to the concern that many residents living outside surge-prone areas will attempt to evacuate in future hurricanes, either crowding local shelters or congesting roads leaving the region. The concern has been expressed not just about residents of south Dade county but about those in other coastal counties as well. There is no doubt a greater *tendency* exists for non-surge residents of south Dade to evacuate now than there was before Andrew, but the extent to which that tendency extends to the Treasure Coast region is only a matter of conjecture. The recommendations in Table 2 acknowledge the fact that there will be evacuation from low risk areas, and Andrew is not likely to increase the number significantly if at all. A sample survey could shed further light on this issue.

All of the figures in Table 2 presume that officials are successful in reaching residents with evacuation notices. Andrew could make that job easier. Residents are likely to pay closer attention to hurricane information now than they did before Andrew, and that attention will probably persist for at least two years.

Timing of Evacuation

Probably the most meaningless hypothetical question that can be asked in a hurricane response survey is "how long would it take before you could be ready to leave?" Therefore the results for this question in the 1982 survey won't even be considered in this analysis. Empirical evidence in evacuation after evacuation demonstrates emphatically that the very same people will leave promptly or slowly depending upon the circumstances of the particular threat. When people believe they have the luxury of taking their time to depart, most tend to do so, even to the point of waiting until the following day to leave rather than travel at night. However, when the urgency of immediate response is communicated to people, they respond very swiftly, even leaving between midnight and daybreak. One other factor is also clear: very few evacuees (less than 20%) leave before officials issue an evacuation notice.

Therefore, people are not going to leave in substantial numbers until someone in a position of authority tells them to and then they will leave as promptly as they are told they must. The urgency of evacuations varies because of the error inherent in hurricane forecasting. If a storm intensifies, increases forward speed, or changes course unexpectedly, it usually becomes more necessary for evacuees to leave quickly.

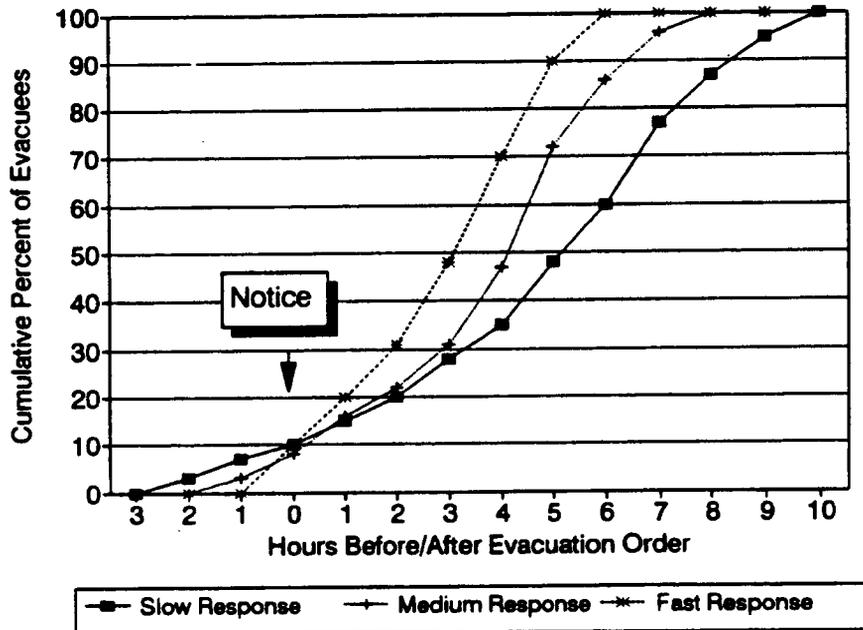

Regardless of the proficiency of emergency management officials, circumstances are going to arise sometimes in which very prompt evacuation is necessary. In other cases the notice will be issued earlier, and evacuation can proceed more leisurely. For planning, the three different timing response curves shown in Figure 1 should be evaluated, because eventually the Treasure Coast will

experience all three. In each threat scenario occupants of low risk areas will tend to wait longer to evacuate than those living in more hazardous locations.

Effect of Andrew

Due to the fact that the public will probably pay greater attention to hurricane information for the foreseeable future, response could be more prompt than it would have been before Andrew. Therefore, the "fast response" curve could become more frequent. Spontaneous evacuation (before officials advise or order it) is still unlikely to exceed 20%, however.

Figure 1. Evacuation Response Curves

Use of Public Shelters

Response in David

Table 3 summarizes public shelter use in hurricane David in 1979. Overall 18% of the evacuees went to public shelters (55% to friends and relatives, 15% to hotels and motels, 12% elsewhere). There appears to have been variation from zone to zone and county to county, but because of the small number of evacuees included in the coastal and interior samples, estimates for those areas are not very reliable. It is clear however, that a substantially larger portion of the evacuees from the interior sample used public shelters than from the middle and coastal zones. Elderly evacuees were somewhat more likely to use public shelters than younger evacuees. The trends are consistent with the general response model. People who evacuate from lower risk areas and elderly retirees are generally more likely to go to public shelters when they leave.

	<u>Coastal</u>	<u>Middle</u>	<u>Interior</u>
AGE			
>65	.24 +/- .16	.19 +/- .07	.62 +/- .23
<65	.08 +/- .07	.15 +/- .05	.45 +/- .14

Table 3. Actual public shelter use in David.

Hypothetical Use of Public Shelters

When asked what sort of shelter they expected to use if they evacuated, far more people said they would use public shelters than actually did in David (Table 4). This is an extremely common finding. In locations where actual evacuations

have been documented and there have also been hypothetical surveys conducted, the hypothetical public shelter use rate is usually double the actual usage.

	<u>Coastal</u>	<u>Middle</u>	<u>Interior</u>
AGE			
>65	.44 +/- .13	.54 +/- .04	.38 +/- .08
<65	.26 +/- .08	.51 +/- .04	.48 +/- .06

Table 4. Intended public shelter use in 1982 survey.

In some studies (but not the Treasure Coast survey), people who said they would use public shelters were asked whether they had friends or relatives in safe locations with whom they could stay if necessary. Most answered affirmatively. Those were then asked whether they might not actually stay with those friends and relatives rather than going to a public shelter. Again, most answered affirmatively, indicating the instability of the hypothetical response.

One reason that actual shelter use tends to be lower than hypothetical is that during hurricane threats, people tend to contact one another, with residents in safe locations often inviting and even urging friends and relatives to come to their houses. Thus options become available that might not have been assumed during a hypothetical interview. It is also likely that as evacuation nears, people consider the pro's and con's of public shelters more carefully, with many deciding in retrospect that public shelter conditions are not so attractive after all.

The Tampa Bay Experience

This is not to say that actual shelter use cannot under unusual circumstances be as high as the hypothetical, because like all other responses,

shelter use varies from threat to threat. A study in the Tampa Bay area indicates just how extreme conditions must be for actual shelter use to even approach results obtained in a hypothetical survey.

In a 1980 survey 38% of a four county sample said they intended to use public shelters if they evacuated, with another 17% saying they didn't know where they would go (Tampa Bay Regional Planning Council, 1981). In subsequent years the Tampa Bay Regional Planning Council conducted one of the most aggressive hurricane awareness efforts ever undertaken. Each summer since 1981 county-specific, large scale, detailed, attractive multicolor maps have been distributed as newspaper inserts and by other means to residents in the four counties. The maps allowed most residents to ascertain whether they lived in areas needing to evacuate in hurricanes of various intensities. The maps also depicted the exact location and address of all public shelters in each county, and an attached sheet indicated the shelter people in various areas should use and described the routes to follow to reach the shelters. That sort of excellent, widely distributed hurricane awareness material must be expected to *increase* the use of public shelters over that which it would have been before the repeated distribution of the maps and accompanying information concerning shelter availability and accessibility.

Moreover, the Elena evacuation in the Tampa Bay area occurred largely after midnight and with a sense of urgency. Near 11 PM, when officials became aware of a revised forecast, residents were told to evacuate and to do so quickly. Those circumstances resulted in more people staying in the local area and using public shelters than will be the case in the majority of evacuations. An evacuation which was expected to take more than 12 hours to complete was accomplished in approximately four.

A study conducted in Pinellas county shortly after Elena found that interviewed evacuees there were about half as likely to use public shelters as the

1981 hypothetical survey had found (Baker, 1987). A later study had similar conclusions for other counties in the region (Nelson et al., 1988). Thus, after several years of new, aggressive public awareness efforts publicizing the location of shelters and how to reach them, an evacuation occurred in unusual circumstances tending to maximize shelter demand. Under those conditions actual shelter use appeared to approach the figure yielded by a hypothetical survey preceding the public education campaign. Even with the awareness effort, most evacuations in the Tampa Bay area would not produce the shelter use resulting from the Elena threat.

<u>INCOME</u>	<u>RISK AREA</u>		
	<u>High</u>	<u>Mod</u>	<u>Low</u>
High	10%	15%	20%
Medium	15%	25%	30%
Low	-	40%	60%

Note:

Mobile home figures will be lower if on-site shelter is available.

Elderly evacuees will be more likely than others to use public shelters.

Table 5. Evacuees going to public shelters: planning assumptions.

Recommendations

Table 5 indicates the public shelter use figures to be used for planning in the Treasure Coast region. Only 12% of the evacuees from high risk areas are likely to use public shelters in most evacuations, and the figure is that high only because more than a third of the residents of high risk areas are over 65 years of

age. In retirement areas the elderly are more likely than other age groups to rely upon public shelters. In moderate risk areas shelter use will be slightly higher: 15% to 20%. In high income areas shelter use will be below 15%, and in low income areas it will be above 20%. In low risk areas people who evacuate (although they are a minority of residents in these areas) are more likely to use public shelters than evacuees from higher risk areas.

In David only about 20% of these residents evacuated, but of those who did, over half said they used public shelters. However, a localized gasoline shortage in 1979 combined with the fact that the evacuation order came fairly late (after 6pm) to cause shelter use in David to be higher than that which will usually occur. About 17% of these interior residents lived in mobile homes, and there is some evidence that mobile home residents tend to use public shelters more than most groups. The newer mobile home parks provide on-site shelter, however. Therefore it is unlikely that more than 40% to 45% of the evacuees will normally use public shelters. One reason that shelter use is higher in low risk areas is that income is usually lower. In high income pockets within these areas, shelter use will be below 20%. Shelter demand in these areas can also be reduced by public information programs pointing out other refuge alternatives.

Shelter selection by evacuees

There is little evidence indicating which shelter evacuees will select. The best indications are that shelter use is based mainly on proximity, familiarity, and social factors. Among evacuees not leaving the local area, most likely to go to a shelter that is near their home, one with which they are familiar (for instance, if their child attends a school being used as a shelter), and one where they believe they will be similar to other evacuees from a socioeconomic standpoint.

Race

Table 5 acknowledges that less affluent evacuees are more likely to use public shelters than others. Recent evidence from hurricane Hugo suggests that there might also be a separate effect due to race. In Hugo black evacuees, regardless of income, were more likely to use public shelters than whites. It is currently unknown whether the same tendency exists in Treasure Coast counties.

Effect of Andrew

There is no evidence at this time to suggest that Andrew will affect the percentage of evacuees using public shelters, although it is possible that experiences with public shelters in Treasure Coast counties in Andrew could have such an effect. Sample surveys would be necessary to document that sort of experience.

Vehicle Use

Not all available vehicles are used when a household evacuates because there is concern about separating the family in traffic. No data was collected in the 1982 survey concerning vehicle use in David. Respondents were asked, however, how many vehicles were present in the household and how many would be used in an evacuation. In the survey residents said they would use 56% of the available vehicles. That figure is lower than most hypothetical surveys find and also lower than that which has been documented in most actual evacuations. For planning a figure of 65% would be more prudent and reasonable. There is no reason to believe that Andrew will affect the behavior.

Leaving the Local Area

No data was collected in 1982 documenting whether evacuees in David left the local area. Local emergency management officials recall that there was a gasoline shortage in the region, however, and that probably deterred a number of evacuees from going to inland locations. The Treasure Coast region wasn't placed under a hurricane warning until 6pm on the day evacuation orders were issued. That was fairly late in the day, resulting in fewer people going inland than might otherwise have.

When asked whether in a hypothetical evacuation they would leave the county, 30% from the coastal sample, 22% from the middle, and 34% from the interior said they would go to another county if they evacuated. The figures are lower than those found in most hypothetical surveys.

In most actual evacuations evacuees from high risk areas are more likely to leave the area than evacuees from other locations, with people in low risk areas being the least likely to go very far. This is a result of several factors. Residents of the highest risk locations are usually more affluent than other people and might have greater mobility and be more able to afford inland motel accommodations. Evacuees from high risk locations also tend to leave earlier than other evacuees, thereby finding themselves with more time to reach more distant destinations. They leave earlier because the threat is more certain in risk areas, and the costs of waiting too long to evacuate are greater. Residents of low risk areas can afford the luxury of waiting until the last minute when they are sure whether a storm is actually going to strike the area.

Recommendations

Table 6 indicates the percentage of evacuees that will leave the local area from each of three risk areas and in each of two threat scenarios. The first threat is a very severe hurricane (Category 3 or greater) in which people are told in plenty of time to evacuate, say 24 hours before expected landfall. More people will leave their own county in that sort of circumstance.

Very Strong Storm, Early Evacuation			Weak Storm, Typical Timing		
<u>Risk Area</u>			<u>Risk Area</u>		
<u>High</u>	<u>Mod</u>	<u>Low</u>	<u>High</u>	<u>Mod</u>	<u>Low</u>
50%	35%	25%	40%	25%	20%

Note:

Last minute evacuation would result in lower rates.

Low income areas 10 percentage points lower.

Table 6. Percent of evacuees leaving local area: planning assumptions.

In the other threat the storm is weaker and people aren't told quite to early to evacuate, although there is ample time for everyone to reach safety. In a last minute, late night evacuation, the percentage of evacuees leaving the local area will be even lower than in this second scenario. Low income and elderly residents will be less likely than other people to leave the area. The figures should be reduced by about 10 percentage points for Indian River County due to the flooding propensity of the main evacuation route leading west.

Effect of Andrew

For a few years Andrew could cause more evacuees to leave the region unless evacuation routes are clogged with traffic. Accordingly, in Table 6 figures

for evacuees leaving the region from high risk areas are 10% higher than they would be otherwise, and those for moderate risk areas are 5% higher.

**POST-ANDREW HURRICANE EVACUATION
BEHAVIORAL ANALYSIS FOR THE
TREASURE COAST REGION OF FLORIDA**

Introduction

In February 1993 a report was prepared for the Treasure Coast region of Florida concerning public response during hurricane threats. The analysis relied upon a reanalysis of data originally collected for the first such report prepared in 1983. The original data included survey findings about public response in Indian River, St. Lucie, and Martin counties in hurricane David in 1979, as well as hypothetical response data from those counties. The 1993 report also employed survey data collected in Palm Beach county as part of the Southeast Florida behavioral analysis prepared in 1990.

When hurricane Andrew threatened south Florida in August of 1993, officials in Palm Beach, Martin, and St. Lucie counties called for evacuation. Thus, Andrew provided an opportunity to document actual response to a recent major hurricane in the region. Actual response data is the most useful in making projections about future evacuation behavior. The extreme destruction caused by Andrew in south Dade county also prompted concerns about how Andrew will affect future response in the Treasure Coast region. Specifically concerns were expressed that many residents of non-surge areas would attempt to evacuate out of the region

in future threats, making evacuation by residents of surge areas more difficult. A new analysis of hurricane evacuation behavior in the Treasure Coast region was conducted to use the new information about how residents responded during Andrew and how their response intentions have been affected by Andrew.

Methodology

Survey Questions

In January and February of 1993, following hurricane Andrew, Florida State University conducted a telephone survey with approximately 1200 residents of Broward, Dade, Monroe, Collier, and Lee counties concerning their response in Andrew and future response intentions. Also in January and February of 1993 Hazards Management Group, for the Jacksonville District of the Corps of Engineers, used essentially the same questionnaire (a.k.a., interview schedule) to conduct an additional 250 interviews in Broward, Dade, and Monroe. The current Treasure Coast study used parts of that same questionnaire, supplemented with additional questions.

The basic questions asked of all respondents appear in Appendix A of this report. The word "SKIP" adjacent to a question number indicates a question asked in the earlier FSU and HMG surveys not asked in the Treasure Coast study. After Question 31 in the basic questionnaire Treasure Coast respondents were asked questions appearing in Appendix B or Appendix C of this report.

Questions in Appendix B, labeled "Section L," were asked of surge-zone residents in the Treasure Coast study. The same questions were asked of surge-zone respondents in Palm Beach county as part of the Southeast Florida Hurricane Evacuation Behavioral Analysis in 1990 and provide a pre-Andrew and post-Andrew reference point concerning future response intentions.

Questions in Appendix C, labeled "Section M," were asked of Treasure Coast residents living inland of Category 3 surge areas. The same questions were asked in a separate study in Broward and Dade counties. The questions were designed to indicate the likelihood of "over-response" by non-surge residents in future hurricane threats.

Sample

A total of 750 telephone interviews were conducted in Palm Beach, Martin, and St. Lucie counties. In each county 100 interviews were completed in the Category 1 surge zone, 100 in the Category 2-3 surge zone, and 50 inland of the Category 3 surge zone. The surge areas were defined as closely as possible to those used when Andrew struck, and might not be those currently in use.

In Palm Beach county the Category 1 zone consisted of the beaches east of the intracoastal waterway. The Category 3 surge zone generally followed U.S. 1, except in the extreme northern part of the county in which it extended well west of U.S. 1 and in the extreme south in which it

extended slightly east of U.S. 1. In Martin the Category 1 area was composed of the barrier island beaches and a strip extending approximately one-half mile inland along the mainland bordering the intracoastal waterway and along the mouth of the St. Lucie River. The Category 3 zone followed U.S. 1. In St. Lucie the Category 1 area was made up of the beaches east of the intracoastal waterway, and the Category 3 zone generally extended inland as far as U.S. 1.

Within each of the above zones streets were selected from street maps, then the streets were looked up in cross-reference telephone directories. Depending upon the length of the street within the zone, a number of phone numbers were selected on the street. Those numbers were then phoned for interviewing. Multiple attempts were made to reach numbers not answering initial calls, and only adults were interviewed. At valid households eventually reached, refusal rates were 19% in Palm Beach, 16% in Martin, and 14% in St. Lucie.

The survey results usually will be reported as percentages -- for example, the percentage of respondents in Palm Beach Category 1 surge areas who evacuated. Readers should remember, however, that the figures reported are based upon samples taken from larger populations. The sample values provide estimates of the values of the larger populations from which they were selected, but are usually not precisely the same as the true population values. In general, the larger the number of people in the sample, the

closer the sample value will be to the true population value. As noted above, 100 interviews were conducted in each county in both the Category 1 and Category 2-3 surge zones, plus 50 in each county inland of Category 3 surge areas. A sample of 100 will provide estimates which one can be 90% "confident" are within 5 to 8 percentage points of the true population values. If only half the sample of 100 say they evacuated in Andrew, however, and those 50 respondents are asked where they went, then response values for the destination variable will be based upon only 50 responses, not 100. With a sample of 50, one can be 90% "confident" of being within 7 to 11 percentage points of the actual population value. A sample of 25 is 90% "accurate" only within 10 to 17 percentage points. Therefore, readers should keep in mind that some estimates provided in this report are more statistically reliable than others. The report will caution the reader when responses are based upon particularly small samples, and in many cases data is not reported at all if it is based on an excessively small number of responses. In certain situations responses from the three counties are combined in order to yield a larger sample base. Combined data should be interpreted with care, however, because no attempt was made to weight the data differentially to reflect differences in county population before combining it.

Evacuation Rates in Andrew

Respondents were asked whether they left their homes to go someplace they believed would be safer when Andrew threatened. The results are given in Table 1. Response in the Category 1 zone was much higher in Palm Beach (72%) than in Martin (38%) and St. Lucie (47%). Although part of the Martin Category 1 zone was west of the intracoastal waterway, response was no different there than east of the waterway. Evacuation rates in the Category 2-3 zones were similar in all three counties: 30% in Palm Beach, 22% in Martin, and 29% in St. Lucie. Few residents inland of the Category 3 surge areas evacuated in any of the counties (7% in Palm Beach, 4% in Martin, and 11% in St. Lucie). Overall (combining the three counties) 52% left their homes in Category 1 areas, 27% in Category 2-3 areas, and 7% in inland areas.

Table 1. Evacuation rates by county and surge zone

	<u>Category 1</u>	<u>Category 2-3</u>	<u>Inland</u>
Palm Beach	72%	30%	7%
Martin	38%	22%	4%
St. Lucie	47%	29%	11%

Explanation for the differences among counties is at least partly attributable to differences in the extent to

were supposed to versus 14% who didn't hear. Seventy-six percent of those who believed the evacuation notice was mandatory left. Among interviewees saying that officials came into their neighborhoods with mandatory evacuation announcements, 85% left.

Other factors affecting response were relatively minor compared to risk area and perception of information from public officials. Mobile home residents were more likely to evacuate than other residents in Category 2-3 locations. People believing that Andrew would have caused their home to flood if the track had been different were much more likely to evacuate than others (63% vs. 35% in Category 1 areas and 37% vs. 16% in Category 2-3 areas). Those saying they had seen an evacuation map or brochure were more likely to evacuate in Category 1 areas but not in Category 2-3 areas. People in both areas were more likely to evacuate if they said they had made hurricane evacuation plans prior to Andrew (58% vs. 39% in Category 1 areas, 33% vs. 20% in Category 2-3 areas). Age of the respondent made no difference in the Category 1 area, but response tended to increase somewhat with age in the Category 2-3 areas (19% for those under 45 vs. 43% for those 65 and over). Length of residence in south Florida made little if any difference in evacuation in Category 2-3 areas but appeared to play a role in Category 1 areas (59% for those living in south Florida less 20 years or less, 43% for those 21 to 30 years, and 34% for those more than 30 years). Having children in

the home made no difference in either the Category 1 or Category 2-3 surge areas. Those owning pets in the Category 1 area responded no differently than those who didn't own pets, but in the Category 2-3 area pet owners were less likely to evacuate (18% vs. 39%). When asked an open-ended question as to why they did not evacuate, however, only 3 respondents mentioned their pets as a reason. Non-Hispanic whites appeared more likely to evacuate than other racial and ethnic groups in the Category 1 area, but not in the Category 2-3 area, although the relatively small number of minorities in the sample makes generalizations tenuous. Income had little if any effect on evacuation in any of areas.

which officials were successful in reaching residents with evacuation notices. Table 2 indicates whether respondents said they heard from officials that they should evacuate. In Palm Beach 46% of the Category 1 respondents said they heard from officials that they were supposed to evacuate, compared to 26% in Martin and 24% in St. Lucie. About the same number of Category 2-3 residents said they also heard official evacuation notices pertaining to them: 44% in Palm Beach, 19% in Martin, and 29% in St. Lucie.

In Palm Beach county, of those who said they heard that they were supposed to evacuate, a little more than half in the Category 1 zone and a little less than half in the Category 2-3 area believed the notices were mandatory. In Martin and St. Lucie less than half believed the notices were mandatory. Overall only 13% of the Category 1 residents and 11% of the Category 2-3 residents said they heard from officials that they *must* evacuate.

Hearing the evacuation notices and believing they were mandatory made a major difference in response. Averaging over the three counties, only 44% of the Category 1 residents who said they didn't hear from officials that they were supposed to evacuate left their homes, compared to 76% who said they did hear they were supposed to leave (Table 3). If they believed the notices were mandatory, 87% left, compared to 66% who believed the notices were only recommendations. Residents reporting that officials

physically came into their neighborhoods announcing that they must leave had even higher response rates (90%).

Table 2. Respondents hearing official evacuation notices.

	<u>Heard Order</u>	<u>Heard Recommendation</u>	<u>Not Sure</u>	<u>Total Heard</u>

Table 3. Effect of evacuation notices on response.

	<u>Cat 1</u>	<u>Cat 2-3</u>
Didn't Hear Official Notice	44%	14%
Heard Official Recommendation	66%	41%
Heard Official Order	87%	76%
Heard Order & Officials Came Through Neighborhood	90%	85%

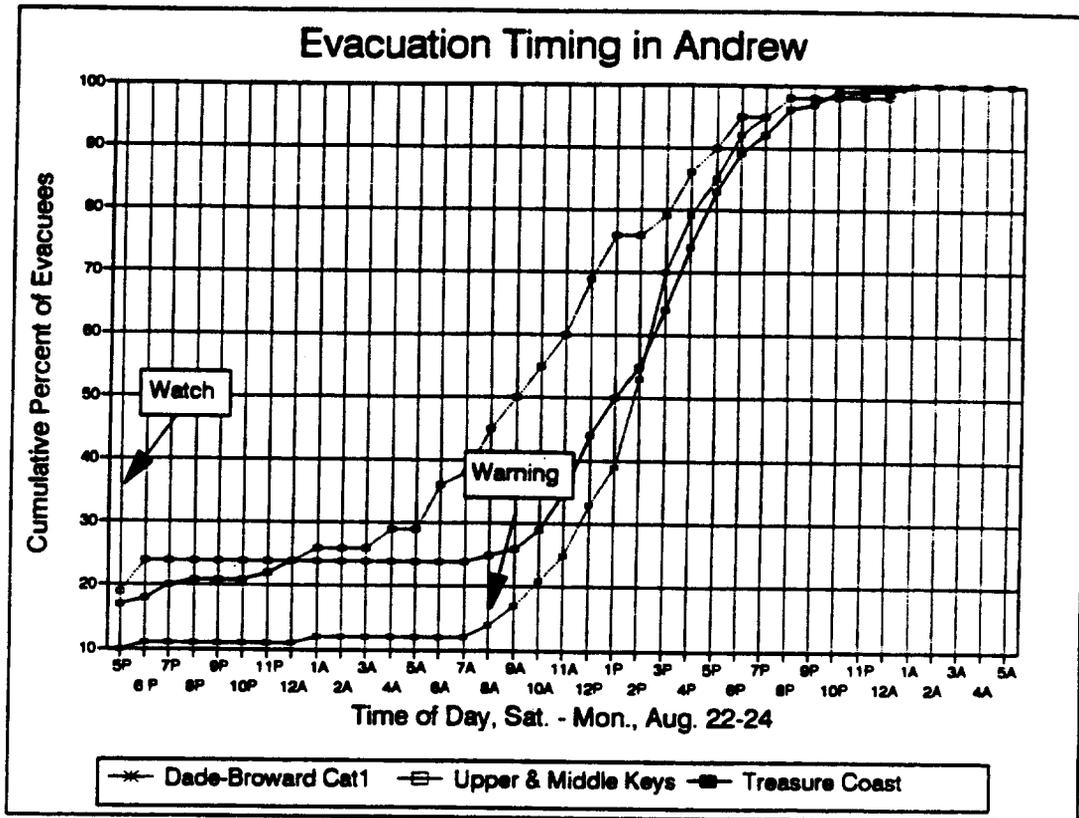

Differences in the Category 2-3 areas were no less dramatic and significant. Fifty-five percent of residents in these areas left if they heard from officials that they

Evacuation Timing in Andrew

Figure 1 is included reluctantly. It depicts the cumulative percentage of evacuees who had left by various times, starting at 5 PM August 21 when a hurricane watch was first issued, and ending at 5 AM August 23 when landfall occurred. Reluctance to include the figure stems from the fact that the Treasure Coast curve was derived from respondents' recollections of what time of day they left their homes more than a year ago. This is much more difficult information to recall precisely than whether one evacuated at all, where one went, and so forth.

The heavy solid curve in Figure 1 indicates reported response in the Treasure Coast region. The lighter dotted curves indicate reported responses in Dade, Broward, and Monroe counties, derived from survey data collected five to six months after Andrew struck. According to the year-after surveys, 25% of the eventual evacuees from the Treasure Coast area said they had left before the hurricane warning was issued. The Treasure Coast curve actually appears ahead of the Dade and Broward curve until Sunday afternoon. This is especially peculiar and suspicious since evacuation notices were issued earlier on Sunday in Dade and Broward than in the Treasure Coast counties (8 AM in Dade and Broward, noon in Martin, 2 PM in Palm Beach, and 4 PM in St. Lucie).

Fig. 1. Cumulative evacuation curves reported in Andrew

It is likely that some of the Treasure Coast respondents recalled that they left substantially earlier than they actually did. In the interview respondents were reminded of the times when the watch and warning were issued but weren't told when (or if) local officials issued evacuation notices. Many respondents probably keyed on the times when the watch and warning were issued. Overall, however, the shape of the curve is as one would expect, and the great majority of evacuees left after warnings were first issued, which is normal.

Types of Refuge Used in Andrew

Table 4 displays the distribution of evacuees by type of refuge used, for locations having at least 25 evacuees. Note that for all locations except the Palm Beach Category 1 area, the figures are statistically unreliable due to the small number of evacuees in those areas. Few evacuees used public shelters in any of the locations. Overall, combining the counties to produce more statistically reliable estimates, only 3% of the evacuees went to public shelters.

Table 4. Type of refuge used in Andrew

	<u>Public Shelter</u>	<u>Friend/ Relative</u>	<u>Hotel/ Motel</u>	<u>Other</u>
Palm Beach				
Cat 1	4%	68%	13%	15%
Cat 2/3	0%	74%	19%	7%
Martin				
Cat 1	4%	59%	11%	26%
St. Lucie				
Cat 1	0%	66%	29%	5%
Cat 2-3	4%	62%	35%	0%
Combined				
Cat 1	3%	66%	17%	14%
Cat 2-3	3%	67%	24%	6%

In all areas, most of those leaving their homes went to the homes of friends or relatives (67% overall). More people went to hotels and motels than public shelters (17% of the evacuees from Category 1 areas and 24% of those from Category 2-3 areas). The remainder were scattered among a variety of places such as churches, workplaces, and second homes.

Tests to identify factors influencing reliance upon public shelters were difficult due to the low number of evacuees using public shelters. People saying they had not made evacuation plans before Andrew were somewhat more likely to go to public shelters, but other tests were inconclusive. In response to an open ended question asking respondents why they didn't evacuate, fewer than 3% indicated that lack of a place to go kept them from evacuating.

Destinations of Evacuees in Andrew

Table 5 indicates the geographical destinations of evacuees. Few evacuees from Palm Beach county left their own county (17% from Category 1 areas and 32% from Category 2-3 areas). Just the opposite was true for Martin. From Category 1 areas 63% left Martin county, and from Category 2-3 areas, 59% left. St. Lucie evacuees were in between, with slightly less than half leaving their county (49% from Category 1 areas and 45% from Category 2-3 areas). As noted elsewhere, however, only the Palm Beach Category 1 figures are reliable due to the small number of evacuees in the other locations. Combining the counties gives more statistically reliable estimates: 38% leaving their own county from Category 1 areas and 44% leaving their own county from Category 2-3 areas.

Of those leaving their own county, 25% went to another county within the Treasure Coast region (including Indian River). Most of those leaving their county (42%) went to interior destinations such as Orlando or to the Tampa Bay area. Fourteen percent went north along I-95, and 18% went south to Broward and Dade.

Transportation in Andrew

In Palm Beach and Martin counties 70% of the available vehicles were used by evacuees. In St. Lucie the figure was 84%. The Palm Beach and Martin figures are within normal ranges documented elsewhere, but the St. Lucie total is very high. In Palm Beach 3% of the evacuees said they pulled trailers, boats, or campers or drove motorhomes, with 2% in Martin and 5% in St. Lucie doing so. Only one respondent indicated they failed to evacuate due to a lack of transportation.

When evacuees were asked whether they required assistance in evacuating only one indicated they required assistance from an agency. Six (out of 225) said they required assistance from someone within their own home, and three said they required help from friends or relatives outside their home. When stayers were asked why they didn't evacuate, three (out of 552) said that caring for a disabled or ill relative kept them from evacuating. Those might have been related to concern about caring for the relatives at shelters rather than concerns about transporting them.

Intentions to Respond in Future Threats

Surge Zones

Residents of surge zones were presented with a hypothetical hurricane threat in which there was a Category 3 hurricane, a hurricane watch was in effect, and local officials had not advised any specific actions. They were told the hurricane watch meant the storm probably wouldn't hit within the next 24 hours if it hit at all, but low places in roads could be flooded before the worst of the hurricane arrived. They were asked whether they would leave their home to go some place safer under those circumstances. (See Appendix B.) Table 6 summarizes the results.

Table 6. Surge residents' intended responses to Category 3 hurricane, watch, no evacuation notice.

	<u>Evacuate</u>	<u>Wait</u>	<u>Don't Know/ Other</u>
Palm Beach			
Cat 1	44%	52%	4%
Cat 2-3	34%	61%	4%
Martin			
Cat 1	49%	50%	2%
Cat 2-3	57%	36%	7%
St. Lucie			
Cat 1	55%	40%	5%
Cat 2-3	58%	36%	4%

Approximately half the respondents from Category 1 areas said they would evacuate (44% from Palm Beach, 49% from Martin, and 55% from St. Lucie). About a third (34%) from the Palm Beach Category 2-3 area said they would leave, but more than half the respondents from Martin (57%) and St. Lucie (58%) Category 2-3 areas said they would evacuate at that time. The same scenario was posed to Palm Beach county respondents in a 1990 telephone survey, with similar results. At that time 56% of the Category 1 residents and 36% of the Category 2-3 residents said they would leave. Residents of Broward and Dade gave very similar responses in the 1990 survey.

Respondents were then told the same storm was now closer, a hurricane warning was in effect, and local officials had ordered their area to evacuate. Rather than asking whether they would evacuate, they were asked where they would go when they evacuated. The format was intended to identify those respondents who felt most strongly about staying, requiring them to point out that they would not evacuate at all.

The results appear in Table 7. The left-hand column lists those who said they would stay. In all instances the figure was 10% or fewer. The lowest was in the St. Lucie Category 1 area where no one said they would refuse to leave. The Palm Beach results regarding stayers were almost identical to those in 1990.

Table 7. Surge residents' intended responses to Category 3 hurricane, warning, evacuation ordered.

	<u>STAY</u>	<u>Public Shelter</u>	<u>Friend/Relative</u>	<u>Hotel/Motel</u>	<u>Other/DK</u>
Palm Beach					
Cat 1	9%	6%	51%	21%	13%
Cat 2-3	10%	12%	33%	18%	26%
Martin					
Cat 1	6%	21%	40%	14%	19%
Cat 2-3	9%	12%	38%	14%	27%
St. Lucie					
Cat 1	0%	11%	43%	26%	20%
Cat 2-3	5%	18%	36%	19%	22%

Intended public shelter use was significantly higher than actual use in Andrew. Intended use varied from a low of 6% in the Palm Beach Category 1 area to a high of 21% in the Martin Category 1 area (which was almost matched by 18% in the St. Lucie Category 2-3 area). Those intending to use public shelters in Palm Beach county were somewhat down from the 1990 survey, however. In the earlier survey 11% of the beach residents said they would use public shelters (6% after Andrew), and 17% of the Category 2-3 residents said they would go to public shelters (12% after Andrew). Overall, more than half (55%) of those saying they would go to public shelters said they had friends or relatives in safe locations with whom they could stay.

accurately for high and moderate risk areas (roughly corresponding to Category 1 and 2-3 zones respectively), for residents who said they heard they were being ordered to evacuate. Although the original report alluded to the fact that evacuation notices had to be communicated effectively in order to maximize response (above levels observed in David, for example), the point was probably not made explicitly enough (except in reference to mobile homes) that the responses listed in the table were dependent upon people receiving and accurately comprehending evacuation notices from officials. If only half the residents in surge areas hear that they are supposed to evacuate, as respondents in Palm Beach county reported, or if only a fourth do so, as respondents in Martin and St. Lucie reported, response rates will be more like those in Andrew than those in Table 17. Emergency management has little control over how effectively and aggressively evacuation notices are actually disseminated, but if a community does not have the resources to go door-to-door or at least go repeatedly into neighborhoods with loudspeakers, evacuation rates will be lower than those in Table 17, probably 25% lower in high and moderate risk areas.

It is also true, however, that the Treasure Coast counties, especially Martin and St. Lucie, were far enough north of the forecast track when the warning was issued that many residents discounted the threat more than they would have if the forecast track had been more in their direction.

If the storm had turned north to the Treasure Coast region, more people would have evacuated but not as early as in Andrew.

The damage caused by Andrew in south Dade county has certainly made the public in all of south Florida more attuned to hurricane information. The same evacuation notice dissemination efforts used in Andrew would probably result in more people saying they heard officials say they should evacuate than said so in Andrew. Many residents inland of surge areas are also more concerned about their safety now than they were before Andrew. How these concerns translate into behavior is a different matter, however.

In Palm Beach county, intended evacuation rates in surge areas are about the same now as in 1990. If comparable data existed for Martin and St. Lucie counties there is no reason to believe response intentions would have changed there since 1990 either. In 1990 in Palm Beach, Broward, Dade, and Monroe counties at least half the residents of Category 1 surge areas said they would leave during a watch before notices from public officials, and about a third of the Category 2-3 residents said the same. In Andrew the actual percentage of the population which evacuated during the watch was a small percentage of those who said they would, and that was also true in Broward, Dade, and Monroe. It is virtually always true: people are far more likely to say they would evacuate in low risk situations than they actually are.

Implications for Future Response

The post-Andrew survey data provides extremely valuable information for reconsidering the behavioral assumptions produced in the February 1993 Hurricane Evacuation Behavioral Analysis for the Treasure Coast Region. However, it must be used carefully. Public response in one hurricane will not usually be the same response in all hurricanes, mainly because future storms and the circumstances surrounding them will be different, but sometimes because experiences in one storm influence future response. Therefore, just as response in David in 1979 was not used as the sole guide prior to Andrew for deriving behavioral assumptions, neither will Andrew now. The best use of Andrew response data is to assess whether it was adequately consistent with responses which should have been anticipated by use of the General Response Model which was derived from analysis of response patterns in a large number of locations in many previous hurricane evacuations.

The survey questions eliciting intended responses to hypothetical hurricane scenarios are useful in making comparisons such as before and after Andrew, between locations, and between scenarios. Intended response data is a notoriously poor predictor of actual response when taken literally and at face value, however. The Andrew response data and post-Andrew intended response data will be used to reassess and refine previously derived behavioral

assumptions for the Treasure Coast Region rather than construct new assumptions from scratch.

Evacuation Rates

The February 1993 report included a table summarizing behavioral assumptions regarding evacuation rates for two hurricane scenarios, for each of three categories of risk area, and two types of housing (mobile homes and housing other than mobile homes). A version of that table appears below as Table 17.

Table 17. Evacuation rates to be used for planning.

Severe Storm Evacuation Ordered in High and Moderate Risk Areas and Mobile Homes			Weak Storm Evacuation Ordered in High Risk Areas Only but All Mobile Homes		
RISK AREA			RISK AREA		
<u>High</u>	<u>Mod</u>	<u>Low</u>	<u>High</u>	<u>Mod</u>	<u>Low</u>
Housing Other Than Mobile Homes					
90%+	75%	15%	85%	40%	10%
Mobile Homes					
95%	90%	80%	90%	75%	65%

Andrew fitted the storm scenario described on the left: severe storm, evacuation ordered in high and moderate risk areas and mobile homes. The values appearing in the original table matched response in Andrew extremely

responses. This question demonstrates how sensitive intended responses can be to variations in information.

A few respondents (as many as 14% in St. Lucie county) said they would go to local shelters, and others (less than 5% overall) said they would go elsewhere within their county. An additional 6% overall said they didn't know where they would go. Three additional questions were asked to gain greater insight into people's beliefs about the safety of various places in their communities.

Respondents were asked whether they thought they would be safe in their own house in a storm like Andrew, even if it were damaged by the storm. They were also asked if they had friends or relatives in their community in whose house they would be safe in a storm like Andrew and if they thought they would be safe in a local public shelter in a storm like Andrew. The results are given in Tables 14, 15, and 16.

Table 14. Inland residents' belief their own house would be safe in storm like Andrew.

	<u>Yes</u>	<u>No</u>	<u>Don't Know/ Depends</u>
Palm Beach	52%	38%	10%
Martin	51%	35%	14%
St. Lucie	41%	45%	14%

Table 15. Inland residents' belief a local friend or relative's house would be safe in storm like Andrew.

	<u>Yes</u>	<u>No</u>	<u>Don't Know/ Depends</u>
Palm Beach	44%	46%	10%
Martin	49%	49%	2%
St. Lucie	33%	63%	4%

Table 16. Inland residents' belief a local shelter would be safe in storm like Andrew.

	<u>Yes</u>	<u>No</u>	<u>Don't Know/ Depends</u>
Palm Beach	53%	33%	14%
Martin	43%	35%	22%
St. Lucie	51%	27%	22%

Except in St. Lucie about half the respondents believed their houses would be safe in a storm like Andrew, which leads to concern about the likely behavior of the other half (more than half in St. Lucie). That is, if people don't believe their houses would be safe, it would seem more likely that they would attempt to go someplace else. Even fewer people believe they have a local friend or relative whose house would be safe in a storm like Andrew, and about the same number of people have confidence in public shelters as have confidence in their own homes. However, the percentage who have confidence neither in their own home, nor a local friend's, nor a local public shelter is only 14%. That is the group most likely to leave the local area.

Table 11. Inland residents' intended responses in Category 3 hurricane, warning, evacuation ordered for Cat 1-3 surge areas and mobile homes only.

	<u>Leave County</u>	<u>Evacuate in County</u>	<u>Wait</u>	<u>Other /DK</u>	<u>STAY</u>
Palm Beach	22%	6%	24%	0%	46%
Martin	20%	4%	14%	4%	57%
St. Lucie	20%	18%	12%	17%	33%

Table 12 indicates the sort of refuge intended evacuees planned to seek. Note that the figures reported in Table 12 are based on very few people saying they would evacuate in any single county. The combined sample is slightly more reliable, indicating that 20% of the intended evacuees planned to go to public shelters, significantly higher than in Andrew.

Table 12. Inland intended evacuees planned refuges in Category 3 hurricane.

	<u>Public Shelter</u>	<u>Friend/ Relative</u>	<u>Hotel/ Motel</u>	<u>Other /DK</u>
Palm Beach	25%	50%	8%	17%
Martin	13%	33%	13%	41%
St. Lucie	23%	33%	17%	27%

In areas where officials are concerned that over-response from inland areas will drive up clearance times to unmanageable levels, it is plausible that officials will use the media to explain why it is unnecessary for residents of non-surge areas to evacuate and why they should not. To

test the impact of that sort of message, respondents were presented with another scenario. They were told that part of the community was being told to evacuate with a strong storm approaching, and officials had appealed to the respondents not to try to evacuate outside their own county. Officials had explained that the respondents' location would definitely not flood, and that if occupants took proper safety measures houses of average construction would probably be safe, even if they suffered major damage. Finally, officials had explained that if people from the respondents' area tried to evacuate outside the county, it would cause roads being used by people evacuating from more dangerous locations to become clogged with traffic, causing no one to be able to get out safely. Responses are given in Table 13.

Table 13. Inland residents' intended responses to official appeals to not evacuate out of county.

	<u>Out Anyway</u>	<u>Local Shelter</u>	<u>Other Local</u>	<u>Stay Home</u>	<u>Other /DK</u>
Palm Beach	10%	2%	6%	75%	6%
Martin	6%	0%	6%	81%	9%
St. Lucie	5%	14%	2%	75%	5%

Few people (5% to 10%) said they would still attempt to leave their local area, and overall these levels were only a third as high as the original intended out-of-county

Appendix C.). They were asked whether they would evacuate out of the county, evacuate within the county, or not evacuate at that time. Responses are given in Table 9. Note that although separate responses are given for each county, there were only 50 respondents in each county. Thus differences among the counties might not be as large as they appear.

Table 9. Inland residents' intended responses to Category 2 hurricane, watch, no evacuation notice.

	<u>Leave County</u>	<u>Evacuate in County</u>	<u>Wait</u>	<u>Other /DK</u>
Palm Beach	12%	8%	72%	6%
Martin	16%	2%	63%	20%
St. Lucie	18%	10%	55%	14%

The majority clearly did not intend to evacuate either out of their county or elsewhere under those circumstances. Those considered to have the greatest impact on clearance times are those leaving their own counties, and very few (12% in Palm Beach, 16% in Martin, and 18% in St. Lucie) said they would do so given the scenario described above.

A second scenario was then described in which all variables were the same except that the storm was a Category 3 with winds of 125 MPH (compared to 100 MPH in the original threat). Responses appear in Table 10. Those intending to go out of county rose in Palm Beach county to 20%, but

response in Martin and St. Lucie changed little if any (16% in Martin and 20% in St. Lucie).

Table 10. Inland residents intended responses to Category 3 hurricane, watch, no evacuation notices.

	<u>Leave County</u>	<u>Evacuate in County</u>	<u>Wait</u>	<u>Other /DK</u>
Palm Beach	20%	8%	68%	4%
Martin	16%	6%	65%	14%
St. Lucie	18%	10%	55%	14%

Finally, respondents were told that the Category 3 storm was closer and a hurricane warning had been posted from Key West to Titusville, meaning that the storm was expected to hit someplace within that area within the next 24 hours. They were told that shelters had been opened and that officials had ordered everyone living in mobile homes and everyone living in Category 1, 2, and 3 storm surge zones to evacuate. Respondents were told that would not include them unless they lived in a mobile home. (None of the inland sample respondents lived in mobile homes.) Table 11 contains the responses.

The new information had little effect on response, particularly on those intending to leave their own county. Intended evacuation out of county was approximately 20% in each county. Table 11 includes a new response category, those who felt certain they wouldn't evacuate at all, as opposed to those who simply wouldn't evacuate at that time.

Table 8 indicates the geographical locations where intended evacuees said they would go. Half the Palm Beach respondents said they would stay in their own county, whereas only 20% of Martin and 25% of St. Lucie interviewees said they would go to destinations within their counties. Although the numbers are different (with a greater percentage of intended evacuees saying they would leave their county than actually did in Andrew), the patterns among counties are similar to those in Andrew, with more evacuees staying in Palm Beach than in Martin and St. Lucie. The total percentages assigned to each destination area in Table 8 are generally lower than those in Andrew because of the number of "don't know" responses in the hypothetical.

Table 8. Surge residents' intended destinations in Category 3 hurricane, warning, evacuation ordered.

<u>DESTINATION</u>	<u>ORIGIN</u>		
	<u>Palm Beach</u>	<u>Martin</u>	<u>St. Lucie</u>
Palm Beach	50%	3%	4%
Martin	0%	20%	2%
St. Lucie	1%	5%	25%
South	4%	14%	4%
North	10%	17%	22%
Inland/ West	20%	23%	20%
Don't Know	15%	18%	23%

In the 1990 survey 67% of the Palm Beach intended evacuees said they would stay in the county, compared to 50% after Andrew. The 1990 figure might not be completely comparable, however, because the 1990 report did not report a "don't know" total. Thus the 67% might have meant 67% of those indicating a specific location. Leaving out the "don't know's" from Table 8, 59% of the Palm Beach intended evacuees identifying a specific destination said they would stay in Palm Beach county.

Areas Inland of Category 3 Surge Zones

The scenarios used in the surge zones were chosen to provide a pre-Andrew and post-Andrew comparison, at least in Palm Beach county. Comparable interviews weren't conducted in inland areas in the 1990 survey, however, so there was no advantage in using the surge zone scenarios in those areas. The goal was to describe threat scenarios with the same sort of information the public would be likely to hear during a real threat, but in abbreviated form.

Residents inland of Category 3 surge areas were initially presented with a Category 2 hurricane with winds of 100 MPH, and they were reminded that Andrew had been a Category 4. There was a hurricane watch in effect for most of the east coast of Florida, meaning the storm could hit someplace on the east coast within the next 36 hours. Public officials had not yet recommended that anyone evacuate, and public shelters were not yet open (See

When the original behavioral survey was performed in the Treasure Coast region in 1982 or 1983 part of the sampling was in inland locations (roughly inland of I-95 in Indian River county and inland of Florida's Turnpike in St. Lucie and Martin). When posed with a hypothetical strong recommendation by a government authority that they evacuate, 95% said they would. In Andrew officials did not strongly recommend that they evacuate, but if they had, far fewer than 95% would have.

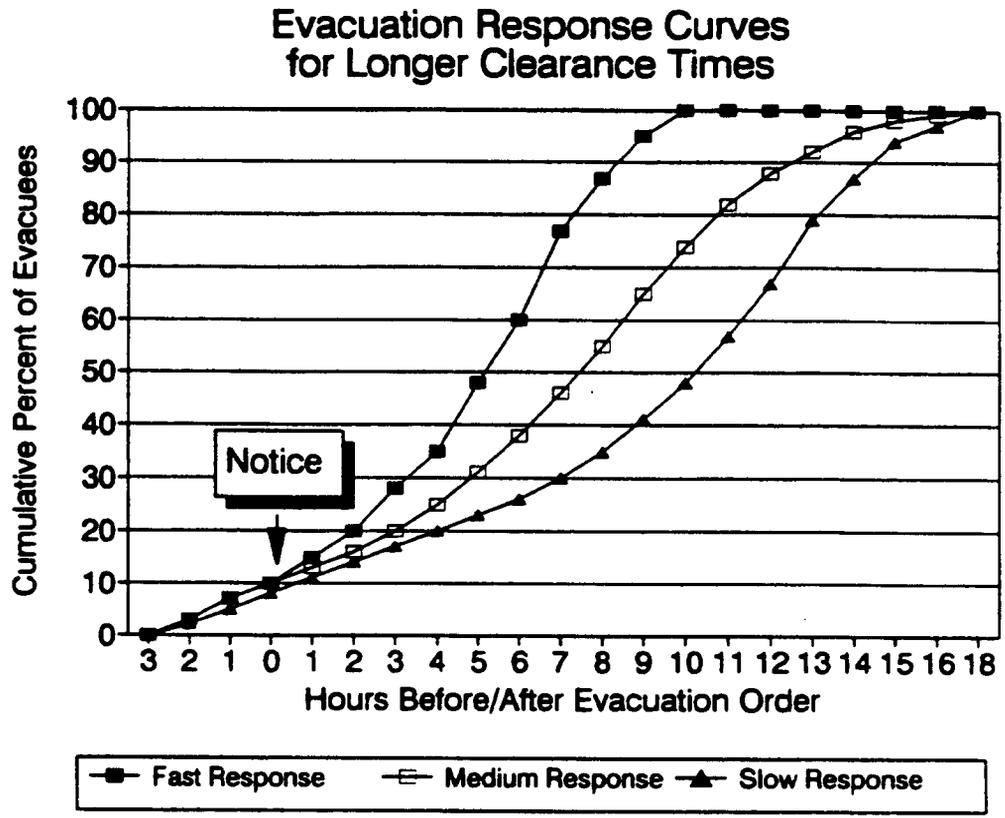

If planners want to err of the side of extreme caution (i.e., assume higher than probable responses) in inland areas, they can use the intended responses in Tables 9, 10, and 11. In fact, however, in most hurricanes the actual number of people evacuating their homes in inland areas will be less than half those values.

Table 17 uses a value of 15% in strong storms and 10% in weak storms in low risk areas. These are actually lower than values appearing in the February 1993 report. The reduction occurs due to a change in the application of the term low risk area. In the earlier document it was described as an area where the primary hazard was wind, but the response figure assigned to it was actually intended to apply to the parts closest to surge areas rather than applying throughout the entire inland area of the county. The new figures should be used for all of the county inland of surge areas.

Evacuation Timing

The February report provided three cumulative response curves: slow, medium, and fast, in relation to how many evacuees would leave relative to the timing of an evacuation notice. Such curves will vary depending upon how long before the projected arrival of the hurricane the evacuation notices are issued. Those times are in turn tied to clearance times. The curves used in the February report are most appropriate for evacuations in which notices are issued no more than 12 to 15 hours before the arrival of tropical storm conditions. They fitted the situation in Andrew in the Treasure Coast counties. It seems probable, however, that there could be storm threats in which evacuation notices are issued earlier, particularly for evacuees leaving the region in a Category 4-5 hurricane when Dade and Broward are also evacuating. In those cases "flatter" curves should be used, and three scenarios are provided in Figure 2 below. They apply to situations in which evacuation notices are issued 18 to 24 hours before tropical storm forces winds are expected to arrive. The fast response curve would occur if evacuees perceived a sense of urgency, the medium curve would usually apply if the evacuation began in morning hours without a sense of urgency, and the slow curve would be more likely to apply if the evacuation notice was issued during evening hours without a sense of urgency.

Fig. 2. Cumulative evacuation response curves for use in planning for evacuations with 18 to 24 hours lead times.

Type of Refuge

Use of public shelters in Andrew was significantly lower than intended shelter use rates as indicated in the original 1982-83 behavioral survey, lower than shelter use in David in 1979, lower than intended shelter use as indicated in the survey conducted for the current study, and

lower than those recommended for planning purposes in the February behavioral analysis report prepared for the region (Table 5 in that report). Intended shelter use rates are always higher than actual use, but the recommendations in the February report were made higher than they otherwise would have been because of the higher than normal shelter use rates documented in David. There is a question now as to whether use in David was an aberration, use in Andrew was an aberration, or whether factors influencing shelter use have simply changed since 1979. One possibility is that officials discourage shelter use more now than in 1979.

If officials want to be extremely liberal in estimating shelter demand, they can use the recommendations appearing in the February document. Indications are, however, that those given in Table 18 will pertain in most evacuations.

Table 18. Public shelter use rates for planning purposes.

	<u>RISK AREA</u>		
<u>INCOME</u>	<u>High</u>	<u>Mod</u>	<u>Low</u>
High	5%	10%	15%
Medium	10%	15%	20%
Low		25%	35%

Note:

Mobile home figures will be lower if on-site shelter is available.
Elderly evacuees will be more likely than others to use public shelters.

Destinations of Evacuees

The percentage of evacuees who will leave the local area is one of the most difficult evacuation behaviors to predict because it varies so much from one region to another. Assuming that Andrew fitted the "very strong storm, early evacuation" scenario, the recommendations in the February report matched behavior in Andrew well in certain locations and circumstances (Palm Beach Cat 2-3 area, for example) and not in others (Palm Beach Cat 1). In general (combining the responses across counties) the recommendations were too high for Category 1 (50% recommended, 38% actual) areas and too low in Cat 2-3 areas (35% recommended, 44% actual). Too few evacuated from inland areas to estimate how many left their counties.

Generalizations are made more difficult because of the differences among counties. Estimates for Martin and St. Lucie are not particularly reliable due to the smaller number of evacuees from those counties, but they do appear to have been different from Palm Beach. The 17% figure leaving Palm Beach county was extremely low in comparison to most evacuations. Only half the Palm Beach intended evacuees from surge areas said they would stay in their own county in the hypothetical Category 3 threat scenario, which is significantly fewer than stayed in Andrew. In Martin and St. Lucie counties only 20% to 25% said they would stay, which is also fewer than stayed in Andrew. (In the

hypothetical scenario 15% to 23% also said they didn't know where they would go, however, and most of those might stay behind.) The higher rates of intention to go out-of-town could be a consequence of Andrew. More might plan to leave due to the destruction observed in Dade county.

When an actual threat develops, however, practical circumstances often interfere with intentions to leave the local area. Even if Andrew has made surge residents more likely to go out of town than they would have before Andrew, fewer will go out of town than anticipate doing so. Table 19 is revised from the February report to indicate slightly higher percentages of evacuees from surge areas leaving their own county. In Palm Beach county the figures will be lower, with 40% of the evacuees going out-of-county from surge areas.

Table 19. Evacuees going out of county.

Very Strong Storm, Early Evacuation			Weak Storm, Typical Timing		
<u>Risk Area</u>			<u>Risk Area</u>		
<u>High</u>	<u>Mod</u>	<u>Low</u>	<u>High</u>	<u>Mod</u>	<u>Low</u>
60%	45%	40%	50%	40%	25%

Note:

Last minute evacuation would result in lower rates.

Low income areas 10 percentage points lower.

An earlier section of this report indicated that despite intentions, the actual percentage of inland residents living in housing other than mobile homes who will evacuate in future threats will only be 15% in severe storms and 10% in weak storms. Of those inland residents who leave their homes, more now are likely to leave their local area than before Andrew. The February behavioral analysis report indicated that 25% of the inland evacuees would leave their county in a strong storm and 20% in a weaker storm. If another evacuation were to occur this year the percentages would be higher and are reflected in Table 19. Over time the out-of-county evacuation rates will become more like those in Table 6 of the February report.

Transportation

The February report recommended that planners assume that 65% of the available vehicles would be used in an evacuation. In Andrew the figure was 70% in Palm Beach and Martin counties but 84% in St. Lucie. The St. Lucie number is much higher than normally observed in hurricane evacuations and could be attributable to the sampling error. It would be reasonable to assume 70% in Martin and Palm Beach and 75% in St. Lucie in the future.

Appendix A

Basic Questionnaire

**HURRICANE ANDREW
RESPONSE QUESTIONNAIRE**

To refresh your memory about dates and times, on Saturday August 22 Hurricane Andrew began to look like it could hit south Florida. At 5 p.m. on Saturday evening the National Hurricane Center issued a *Hurricane Watch* for the east coast of Florida. At 8 a.m. the following morning – i.e., Sunday morning – the Hurricane Center issued a *Hurricane Warning*. Landfall occurred early Monday morning, around 5 a.m.

1. Were you in South Florida (i.e., not out-of-town) when Andrew began to threaten this area?

IF NO, ASK IF ANYONE ELSE IN THE HOUSEHOLD WAS PRESENT AND ASK TO SPEAK TO THEM.

IF NO ONE IN THE HOUSEHOLD WAS PRESENT AND AREA IS 71, 72, 81, 82, 91 OR 92 (SECTION L) TERMINATE INTERVIEW.

IF NO ONE IN THE HOUSEHOLD WAS PRESENT AND AREA IS 04, 05, 06, 07, 08, 09, 61, 62, 73, 83, OR 93 (SECTION M) GO TO QUESTION 23.

IF YES, BEGIN WITH QUESTION 1a.

- 1a. Were you living at this address at the time?

1 Yes
 5 No

IF NO: Where were you living at that time?

Name of city or community _____

In which county is that? _____

What is the zip code? _____

2. I'd like to ask you about when Andrew threatened this area – that is, on Saturday August 22 or Sunday the 23rd. Did you leave your home to go someplace safer before the hurricane?

1 Yes (GO. TO Q. 4)
 5 No (GO TO Q. 3)
 9 Don't Know

3. What made you decide not to go anyplace else?

CODE UP TO 3 RESPONSES	
<input type="checkbox"/> 01 Storm not severe/house adequate	<input type="checkbox"/> 09 Had no place to go
<input type="checkbox"/> 02 Officials said evacuation unnecessary	<input type="checkbox"/> 10 Wanted to protect property from looters
<input type="checkbox"/> 03 Media said evacuation unnecessary	<input type="checkbox"/> 11 Wanted to protect property from storm
<input type="checkbox"/> 04 Friend/relative said evacuation unnecessary	<input type="checkbox"/> 12 Left unnecessarily in past storms
<input type="checkbox"/> 05 Officials didn't say to evacuate	<input type="checkbox"/> 13 Job required staying
<input type="checkbox"/> 06 Probabilities indicated low chance of hit	<input type="checkbox"/> 14 Too dangerous to evacuate

Surge Area Supplementary Questions

SECTION L

Use Only If Area Is
71, 72, 81, 82, 84, 91 or 92

Let's say there's a pretty bad hurricane in the Atlantic or Caribbean, say a Category 3, a dangerous storm, and it looks like it could hit this area. The National Hurricane Center has issued a hurricane watch for this area – that means the storm probably won't hit within the next 24 hours if it hits at all, but low places in roads could be flooded before the worst of the hurricane arrived. Local officials haven't advised any specific actions yet.

- L1. I know you can't say for sure what you would do in that situation, but do you think you and the rest of the people living with you would evacuate under those circumstances? (when I say evacuate, I mean going someplace you think would be safer if the hurricane hit; it could be nearby or far away).

- | |
|--|
| <input type="checkbox"/> 01 Yes, probably would leave
<input type="checkbox"/> 05 No, wouldn't leave then

Inland Area Supplementary Questions

SECTION M

Use Only If Area Is
04, 05, 06, 07, 08, 09, 61, 62, 73, 83, 93

- M1.** Suppose there is a Category 2 hurricane in the Atlantic or Caribbean with winds of 100 MPH. By comparison, Andrew was a Category 4. The National Hurricane Center has issued a hurricane watch for most of the east coast of Florida, including this area, which means it could hit someplace on Florida's east coast within the next 36 hours. Public officials have not yet recommended that anyone evacuate, and public shelters are not yet open. What do you think you would do?

- 1 Evacuate out of this county (Where? _____)

3 Evacuate to someplace within the county

5 Wouldn't evacuate at this time

7 Other

(Specify)

9 Don't Know

- M2.** What if the situation were exactly the same, except that it's a stronger storm, a Category 3 hurricane, with winds of 125 MPH. Everything else is the same: a hurricane watch for most of the east coast of Florida, shelters not open, and no evacuation recommendation yet from public officials. What do you think you would do?

- 1 Evacuate out of this county (Where? _____)

3 Evacuate to someplace within the county

5 Wouldn't evacuate at this time

7 Other

(Specify)

9 Don't Know

- M3.** Now let's say that same storm is closer. It's still a Category 3. A Hurricane Warning has been posted from Key West to Titusville, meaning that the storm is expected to hit someplace in that area within the next 24 hours. Shelters have been opened, and public officials have ordered that everyone living in mobile homes and everyone living in Hurricane Category 1, 2, or 3 storm surge areas evacuate. That would not include you, unless you live in a mobile home. What would you do?

- 1 Evacuate out of this county (Where? _____)

3 Evacuate to someplace within the county

5 Would wait longer to decide

6 Wouldn't evacuate at all

7 Other

(Specify)

9 Don't Know

FOR THOSE SAYING THEY WOULD EVACUATE (OPTIONS 1 OR 3):

186

M3b. Would you go to a public shelter or someplace else?

<input type="checkbox"/> 1 Public Shelter
<input type="checkbox"/> 3 Friend or Relative
<input type="checkbox"/> 5 Hotel/Motel
<input type="checkbox"/> 7 Other

(Specify)
<input type="checkbox"/> 9 Don't Know

M4. Suppose part of the community was being told to evacuate with a strong storm approaching, and local officials appealed to you not to try to evacuate outside your own county. They said your location will definitely not flood, even if the storm hits nearby. They said that if you live in a house of average construction and if you take proper safety measures, you will probably be safe, even if your house suffers major damage. They also said that if people from your area try to evacuate outside the county it will cause the roads being used by people evacuating from more dangerous locations to become clogged with traffic, and no one will be able to get out safely. What would you do?

<input type="checkbox"/> 1 Evacuate out of county anyway
<input type="checkbox"/> 3 Evacuate to local public shelter
<input type="checkbox"/> 5 Evacuate elsewhere locally
<input type="checkbox"/> 7 Would stay home
<input type="checkbox"/> 8 Other
<input type="checkbox"/> 9 Don't Know

M5. In a storm like Andrew, do you think you would be safe in your own house, even if it were damaged by the storm?

<input type="checkbox"/> 1 Yes
<input type="checkbox"/> 5 No
<input type="checkbox"/> 6 It depends
<input type="checkbox"/> 7 Other
<input type="checkbox"/> 9 Don't Know

M6. In a storm like Andrew, do you have a friend or relative in this community in whose house you would be safe, even if it were damaged?

<input type="checkbox"/> 1 Yes
<input type="checkbox"/> 5 No
<input type="checkbox"/> 6 It depends
<input type="checkbox"/> 7 Other
<input type="checkbox"/> 9 Don't Know

APPENDIX D

DECISION ARC METHOD

A. General.

A hurricane evacuation should be completed prior to the arrival of sustained 34 knot (gale-force) winds or the onset of storm surge inundation, whichever occurs first. In the Treasure Coast Region Hurricane Evacuation Study area, the limiting factor for hurricane evacuation is the arrival of sustained 34 knot winds.

The clearance time is the time required to clear the roadways of all evacuating vehicles, or, the time necessary for a safe evacuation. Therefore, clearance time is measured in hours required prior to the arrival of sustained 34 knot winds. Clearance times are based primarily on three variables: (1) the Saffir/Simpson hurricane category, (2) the expected evacuee response rate, and (3) the tourist occupancy situation.

Decision Arcs are simply clearance times converted to distance by accounting for the forward speed of the hurricane. To translate a clearance time into nautical miles (a Decision Arc distance) for use with a Decision Arc Map, a simple calculation of multiplying the clearance time by the forward speed of the hurricane in knots is necessary. This calculation yields the distance in nautical miles that the 34 knot wind field will move while the evacuation is underway. For convenience, a Decision Arc table that converts an array of clearance times and forward speeds to respective Decision Arcs provided in Appendix A.

B. Should Evacuation Be Recommended?

Probability values shown in the National Hurricane Center's Public Advisory describe in percentages the chance that the center of a storm will pass within 65 nautical miles of the listed locations. To check the relative probability for a particular area, the total probability value for the closest location, shown on the right side of the probability table in the Public Advisory, should be compared to other locations. A comparison should also be made with the possible maximums shown in Table 7-1 the listing of maximum probability values included in Appendix A. There is no one threshold probability which should prompt an

evacuation under any and every hurricane threat. The size and intensity of the storm, as well as its anticipated approach track will need to be considered. Decisions for or against evacuation should be coordinated with the Florida State Police Office Management and the National Weather Service.

C. When Evacuation Should Begin.

As a hurricane approaches, the Decision Arc Method requires officials to make an evacuation decision prior to the time at which the radius of sustained 34 knot winds touches the appropriate Decision Arc (the Decision Point). For example, with a clearance time of 15 hours, and a hurricane forward speed of 25 knots, the evacuation should be initiated before the sustained 34 knot winds approach within 400 nautical miles (arc "T" on the Decision Arc Map). Once the sustained 34 knot winds move across the Decision Arc (within 400 miles of your location), there may not be sufficient time to safely evacuate the affected population.

As mobilization activities are proceeding prior to the Decision Point, consideration should also be given to the need for the traffic control measures discussed in Chapter 6, particularly any reversing of traffic. The decision to employ these strategies will have to be made simultaneously with the decision to evacuate and will itself influence the decision when to evacuate.

D. Evacuation Decision Worksheet.

The Decision Arc Method Worksheet is designed to guide the decision-maker through the Decision Arc Method. Also included are the Decision Arc Table, sample National Hurricane Center marine and public advisories, a time conversion table and the four county Decision Arc Maps.

DECISION ARC METHOD

EVACUATION DECISION WORKSHEET

The following procedure has been developed to provide assistance in determining, for a given jurisdiction, **IF** an evacuation should be initiated and **WHEN** an evacuation decision must be made. The National Weather Service (NWS) hurricane probability listing included in the Public Advisory is used to assist in this decision making process (see sample Public Advisory).

There are five basic "tools" needed in this evacuation decision procedure: (1) Decision Arc Map; (2) Decision Arc Table; (3) transparent STORM disk; (4) the NWS Marine Advisory (usually issued every 6 hours); (5) the NWS Public Advisory.

PROCEDURE

1. From the NWS Marine Advisory, plot the last reported position of the hurricane eye on the appropriate Decision Arc Map. [There are four decision arc maps: Vero Beach; St. Lucie; Stuart; and, West Palm Beach. Use the one on which the center of the decision arcs is nearest your area.] Note the position with date/time. ZULU time (Greenwich mean time or UTC [Universal Coordinated Time]) used in the advisory should be converted to eastern daylight time by subtracting four (4) hours (see Table 7-3 for conversion of times). Plot and notate the five forecast positions of the hurricane from the advisory.
2. From the Marine Advisory, note the maximum radius of 34 knot winds (observed or forecast), the maximum sustained wind speed (observed or forecast), and the current forward speed. Plot the maximum radius of 34 knot winds onto the STORM disk.
3. Using the maximum sustained wind speed previously noted, enter the Saffir/Simpson hurricane scale table (Table 2-2) and determine the category of the approaching hurricane.
4. Consult the clearance time table (Table 6-7) for your county. Select the appropriate clearance time based on scenario, seasonal occupancy, background traffic, etc.

5. Determine the forecast forward speed of the hurricane in knots. The forecast speed can be determined by measuring the distance in nautical miles between the first and second forecast positions and dividing that distance by 12 [forecast positions are provided for 12 hour intervals]. Compare the forecast forward speed to the current forward speed noted previously. A forecast speed greater than the current forward speed will indicate that the hurricane is forecast to accelerate, reducing the time available to the decision-maker. If clearance times for a locality are very high the forecast forward speed should be determined by measuring the distance between the first forecast position and the forecast position nearest your locality and dividing by the number of hours between forecast positions, e.g. 24 or 36. This will provide the forecast speed for the entire progress of the hurricane toward your location.
6. With the appropriate clearance time, and the greater of the current or forecast forward speeds, enter the Decision Arc table (Table 7-2) and select the recommended Decision Arc. Mark this arc on the county Decision Arc Map.
7. Using the center of the STORM as the hurricane eye, locate the STORM on the Decision Arc Map at the last reported hurricane position. Determine if the radius of 34 knot winds falls within the selected Decision Arc; i.e., past the Decision Point (the point at which the radius of 34 knot winds crosses into the selected Decision Arc). If so, available traffic control measures should be implemented and public advisories issued in order to ensure a prompt public response and completion of the evacuation prior to the arrival of sustained 34 knot winds.
8. Move the STORM to the first forecast position. Determine if the radius of 34 knot winds is past the Decision Point. If so, the Decision Point will be reached prior to the hurricane eye reaching the first forecast position.
9. Estimate the hours remaining before a decision must be made by dividing the number of nautical miles between the radius of 34 knot winds and the Decision Point by the forward speed used for the Decision Arc table. Determine if the next NWS Marine Advisory will be received prior to the Decision Point.
10. Compare probabilities shown in the Public Advisory to determine whether an evacuation is now necessary or is likely to become necessary (See Note [c.] next page). Determine how an evacuation of your county would affect the readiness of other counties, and when other counties should be notified. Check inundation maps to determine where flooding may occur, and evacuation zone maps for zones that

should prepare to evacuate.

11. At the Decision Point, check the Public Advisory probability table for your location. There is no one threshold probability which should prompt an evacuation under any and every hurricane threat (See Note [c.] below). The size and intensity of the storm, as well as its approach track will need to be considered.
12. Steps 1 through 10 should be repeated after each NWS advisory until a decision is made by the county or the threat of hurricane impacts has passed.

NOTES

- a. As new information becomes available in subsequent NWS advisories, evacuation operations should progress so that, if evacuation becomes necessary, the recommendation to evacuate can be given at the Decision Point. It should be noted that there is no built-in provision in the Decision Arc Method to allow time for evacuation decision-making or for mobilizing support personnel. These activities should be completed prior to the Decision Point.
- b. Because information given in the Marine Advisory is in nautical miles and knots, the Decision Arc Maps and STORM have a nautical miles scale. When utilizing hurricane information from sources other than the Marine Advisory, care should be taken to assure that distances are given in, or converted, to nautical miles and speeds to knots. Statute miles can be converted to nautical miles by dividing the statute miles value by 1.15. Similarly, miles per hour can be converted to knots by dividing the miles per hour value by 1.15. Statute mile/nautical mile conversions and mile per hour/knot conversions are shown on the next page.
- c. Probability values shown in the Public Advisory describe, in percentages, the chance that the center of a storm will pass within 65 miles of the listed locations. To check the relative probability for your particular area, the total probability value for the closest location, shown on the right side of the probability table in the Public Advisory, should be compared to other locations. A comparison should also be made with the possible maximums for the applicable forecast period shown in the table of maximum probability values listed on Table 7-1. These comparisons will show the relative vulnerability of your location to adjacent locations and to the maximum possible probability.
- d. Steps 3. and 4. above refer to the intensity of a threatening hurricane and to clearance times that are based, among other factors, on hurricane intensity. Evacuation decision makers may wish to take into account that the storm direction may not be the worst case direction. They may want to refer to these differences in potential inundation in designating areas that should be evacuated and in choosing clearance times. Note, however, that through-county clearance times will be dependent on scenarios utilized in other counties. These decisions should be coordinated between the counties and the Florida DCA, Emergency Management Division.

TABLE 7-1

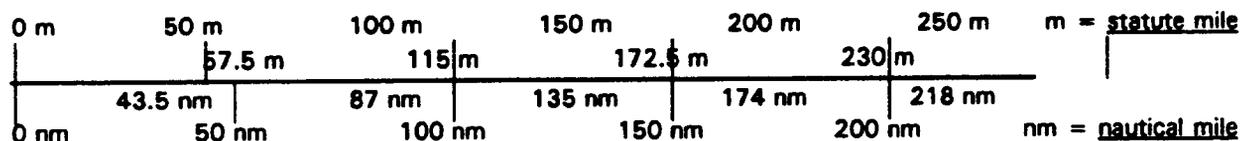

MAXIMUM PUBLIC ADVISORY PROBABILITY VALUES

FORECAST PERIOD	MAXIMUM PROBABILITY
72 Hours	10 %
60	11
48	13
36	20
30	27
24	35
18	45
12	60

Probabilities listed are the maximum assigned to any location in advance of predicted impact. **To illustrate:** the National Hurricane Center would not assign a higher than 35% probability that a hurricane would strike West Palm Beach in 24 hours, or a higher than 20% probability that a hurricane would strike in 36 hours.

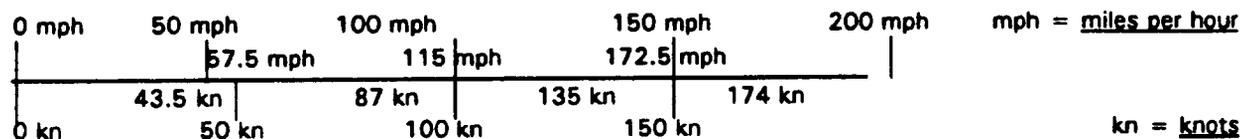

STATUTE MILES / NAUTICAL MILES

1 STATUTE MILE = .87 NAUTICAL MILES
 1 NAUTICAL MILE = 1.15 STATUTE MILES

MILES PER HOUR / KNOTS

1 MILE PER HOUR = .87 KNOTS
 1 KNOT = 1.15 MILES PER HOUR

BULLETIN

HURRICANE HUGO ADVISORY NUMBER 38

NATIONAL WEATHER SERVICE MIAMI FL

6 AM EDT WED SEP 20 1989

A TROPICAL STORM WARNING IS IN EFFECT FOR THE CENTRAL AND NORTHWESTERN BAHAMAS AND IS DISCONTINUED FOR THE SOUTHEASTERN BAHAMAS.

AT 6 AM EDT THE CENTER OF HUGO WAS LOCATED NEAR LATITUDE 24.9 NORTH LONGITUDE 70.5 WEST OR ABOUT 435 MILES EAST OF NASSAU IN THE BAHAMAS.

THE CENTER OF HUGO HAS BEEN MOVING TOWARD THE NORTHWEST AT 12 MPH AND THIS GENERAL MOTION IS EXPECTED TO CONTINUE FOR THE NEXT 24 HOURS.

MAXIMUM SUSTAINED WINDS ARE NEAR 105 MPH AND LITTLE CHANGE IN STRENGTH IS LIKELY TODAY. HURRICANE FORCE WINDS EXTEND OUTWARD UP TO 60 MILES FROM THE CENTER AND TROPICAL STORM FORCE WINDS EXTEND OUTWARD UP TO 200 MILES. THE LATEST MINIMUM PRESSURE REPORTED BY AN AIR FORCE RECONNAISSANCE PLANE IS 957 MILLIBARS...28.26 INCHES.

REPEATING THE 6 AM EDT POSITION...24.9N...70.5W. MOVEMENT...NORTHWESTWARD AT 12 MPH. MAXIMUM SUSTAINED WINDS...105 MPH. CENTRAL PRESSURE...957 MB.

THE NEXT ADVISORY WILL BE ISSUED BY THE NATIONAL HURRICANE CENTER AT NOON EDT WITH AN INTERMEDIATE ADVISORY AT 9 AM.

(CONTINUED)

* This advisory was issued approximately 42 hours before Hurricane Hugo struck the South Carolina coast near midnight on September 21, 1989.

TRANSPORTATION MODEL SUPPORT MATERIALS

Treasure Coast Region Hurricane Evacuation Study

This document serves as a supplement to the Transportation Analysis Chapter of the Treasure Coast Technical Data Report published by the U.S. Army Corps of Engineers in early summer of 1994. Computer data files for Indian River, St. Lucie, Martin, and Palm Beach Counties are included and serve as back-up to the analysis assumptions and results presented in the Technical Data Report.

Computer data files are organized by the following categories:

1. 1990 Estimated Dwelling Unit Data by County Census Tract/TAZ
2. Dwelling Unit Data by Evacuation Zone by County
3. Trip Generation Runs by Storm Scenario by County
4. Representative Total Triptables showing Zone to Zone Vehicle Movements by Storm Scenario
5. Roadway Link Files by County
6. Zone to Zone Path Files by County
7. Evacuating Vehicle Trip Assignments by Link by Storm Scenario by County
8. Sample Clearance Time Runs

A brief description of each category of data is provided.

1990 Estimated Dwelling Unit Data by County Sub-Area

These data files by county show the Census Tracts or traffic analysis zones (TAZs) (depending on availability) and corresponding dwelling unit data. Each TAZ or Census Tract is listed along with the evacuation zone it falls within, the portion of the TAZ or Census Tract within that evacuation zone, and an estimate of total dwelling units, mobile home units, and tourist related units. Annex A provides this data.

Dwelling Unit Data by Evacuation Zone

These data files show the total dwelling units, mobile home units, and tourist related units for each evacuation zone. The files were produced by adding together data for Census Tracts or TAZs which fell within a common evacuation zone. Annex B provides this data.

Trip Generation Runs by Storm Scenario

These computer generated sheets show the evacuating people and vehicles produced by each evacuation zone. The totals by zone are then split by four destination types (local public shelter, friend or relative's home, hotel/motel unit, and out of county). Trip generation runs were accomplished by applying socioeconomic and behavioral assumptions to the zonal data shown in Annex B. Since assumptions and resulting evacuation statistics change by storm scenario, sheets are provided by county for every storm scenario. The specific behavioral

and socioeconomic assumptions for each scenario are summarized on the last sheet of each trip generation run. Annex C provides this data.

Representative Total Triptable Showing Zone to Zone Vehicle Movements

Triptable showing zone to zone vehicle movements were produced for each of the four destination types by storm scenario. By adding the public shelter, hotel/motel, friend/relative's home and out of county triptables together, a total triptable was produced for each storm scenario. The total triptable provides all evacuation trip interchanges within the county for the in-county to in-county and in-county to out-of-county evacuation travel patterns. Total triptable printouts by county are provided in Annex D.

Roadway Link Files by County

Each roadway segment in each county's evacuation network was given a letter name. The characteristics of each link were then defined by general facility type and number of travel lanes. Based on current FDOT tables, characteristics were translated into a generalized maximum hourly directional service volume (at Level of Service D) for each roadway segment. Annex E provides this data for each county's evacuation network.

Zone to Zone Path Files by County

These files show the route(s) assumed for evacuation traffic leaving an evacuation zone and travelling to another evacuation zone or to some exit point at the county line. Routes are specified by a series of link names with a single digit number in front of the link name. The number indicates the portion of zone to zone trips assumed to use that link. A zero indicates 100% - a one indicates 10%, a two indicates 20%, a three indicates 30%, etc. Annex F provides this data.

Evacuating Vehicle Trip Assignments by Link by Storm Scenario

Annex G provides the assigned evacuating vehicle figures for all roadway segments for each storm scenario. In addition, the sheets provide a volume-capacity ration calculated for each link. Those roadway segments with the highest volume-capacity ratios were identified as candidate critical links for each county. Critical links control the flow of evacuation traffic during a hurricane evacuation and are the key areas for traffic flow monitoring.

Sample Clearance Time Runs

Annex H provides sample clearance time runs for various storm scenarios in each county. A specific run shows an hour by hour glimpse of traffic at a critical link assuming a certain response rate (rapid, medium, or slow) and an hourly service volume. The vehicle volumes loaded through the critical link correspond to the level of traffic expected for a certain storm scenario. Background traffic is added in as a portion of average daily directional traffic at the link.

FILE/SCENARIO NOMENCLATURE

Beginning with the files contained in Annex D, the reader will note many files containing six letter name which signifies the state name, study name, county name, storm scenarios, seasonal occupancy and type of evacuation movement. Specifically the following letters were assigned to file names as shown below:

State

F - Florida

Study

T - Treasure Coast

County

I - Indian River

S - St. Lucie

M - Martin

P - Palm Beach

Storm Scenario

A (grouping of storm intensities varies

B by county - see Technical Data Report)

C

D

Seasonal Occupancy

L - Low

H - High

Trip Type/Purpose

P - to local public shelter

H - to local hotel/motel

F - to local friend's home

O - to out of county

T - total of P+H+F +O (all trips)
